RANK-TWO GRAPHS WHOSE $C^*$-ALGEBRAS ARE DIRECT LIMITS OF CIRCLE ALGEBRAS

DAVID PASK, IAIN RAEBURN, MIKAEL RØRDAM, AND AIDAN SIMS

Abstract. We describe a class of rank-2 graphs whose $C^*$-algebras are AT algebras. For a subclass which we call rank-2 Bratteli diagrams, we compute the $K$-theory of the $C^*$-algebra. We identify rank-2 Bratteli diagrams whose $C^*$-algebras are simple and have real-rank zero, and characterise the $K$-invariants achieved by such algebras. We give examples of rank-2 Bratteli diagrams whose $C^*$-algebras contain as full corners the irrational rotation algebras and the Bunce-Deddens algebras.

1. Introduction

The $C^*$-algebras of directed graphs are generalisations of the Cuntz-Krieger algebras of finite $\{0,1\}$-matrices. Graph algebras have an attractive structure theory in which algebraic properties of the $C^*$-algebra are determined by easily visualised properties of the underlying graph. (This theory is summarised in [23].) In particular, it is now easy to decide whether a given graph algebra is simple and purely infinite, and a theorem of Szymański [33] says that every Kirchberg algebra with torsion-free $K_1$ is isomorphic to a corner in a graph algebra. Each AF algebra $A$ can also be realised as a corner in the graph algebra of a Bratteli diagram for $A$ [6, 33]. But this is all we can do: the dichotomy of [19] says that every simple graph algebra is either purely infinite or AF, and a theorem of [26] says that every graph algebra has torsion-free $K_1$.

Higher-rank analogues of Cuntz-Krieger algebras and graph algebras have been introduced and studied by Robertson-Steger [28] and Kumjian-Pask [18], and are currently attracting a good deal of attention (see [13, 16, 17, 25, 32], for example). The theory of higher-rank graph algebras mirrors in many respects the theory of ordinary graph algebras, and we have good criteria for deciding when the $C^*$-algebra of a higher-rank graph is simple or purely infinite [18]. Since these algebras include tensor products of graph algebras, the $K_1$-group of such an algebra can have torsion, so these algebras include more models of Kirchberg algebras than ordinary graph algebras. However, it is not obvious which finite $C^*$-algebras can be realised as the $C^*$-algebras of higher-rank graphs. Indeed, we are not aware of any results in this direction.

Here we discuss a class of rank-2 graphs whose $C^*$-algebras are AT algebras. We specify a 2-graph $\Lambda$ using a pair of coloured graphs which we call the blue graph and the red graph with a common vertex set together with a factorisation property which
identifies each red-blue path of length 2 with a blue-red path. In the 2-graphs which we construct, the blue graph is a Bratteli diagram and the red graph partitions the vertices in each level of the diagram into a collection of disjoint cycles. The C*-algebra of such a rank-2 Bratteli diagram Λ then has a natural inductive structure. We prove that \( C^*(Λ) \) is always an AT algebra with nontrivial \( K_1 \)-group, and in particular is neither purely infinite nor AF. We compute the \( K \)-theory of \( C^*(Λ) \), and produce conditions which ensure that \( C^*(Λ) \) is simple with real-rank zero. Using these results and Elliott’s classification theorem, we identify rank-2 Bratteli diagrams whose C*-algebras contain as full corners the Bunce-Deddens algebras and the irrational rotation algebras. Under the additional hypothesis that all red cycles in Λ have length 1, we improve our analysis of the real rank of \( C^*(Λ) \), and describe the trace simplex.

The paper is organised as follows. In Section 2 we briefly recap the standard definitions and notation for \( k \)-graphs and their C*-algebras. In Section 3 we describe a class of 2-graphs Λ whose C*-algebras are AT algebras. The blue graph of such a 2-graph Λ is a graph with no cycles. The red graph consists of a union of disjoint isolated cycles. Very roughly speaking, the red cycles in Λ give rise to unitaries in \( C^*(Λ) \) while finite collections of blue paths index matrix units in \( C^*(Λ) \). So carefully constructed finite subgraphs of Λ correspond to subalgebras of \( C^*(Λ) \) which are isomorphic to direct sums of matrix algebras over \( C(\mathbb{T}) \). We write \( C^*(Λ) \) as the increasing union of these circle algebras to show that \( C^*(Λ) \) is AT (Theorem 3.1).

In Section 4 we assume further that the blue graph is a Bratteli diagram and that the red graph respects the inductive structure of the diagram, and call the resulting 2-graphs rank-2 Bratteli diagrams. In Theorem 4.3 we compute the \( K \)-theory of \( C^*(Λ) \) for a rank-2 Bratteli diagram Λ. Our arguments are elementary and do not depend on the computations of \( K \)-theory for general 2-graph algebras [29, 12]. The \( K \)-theory calculation shows in particular that \( K_1(C^*(Λ)) \) is isomorphic to a subgroup \( G \) of \( K_0(C^*(Λ)) \) such that \( K_0(C^*(Λ))/G \) has rank zero. We also establish a bijection between the gauge-invariant ideals of \( C^*(Λ) \) and the order ideals of the dimension group \( K_0(C^*(Λ)) \).

Elliott’s classification theorem for AT algebras says that each AT algebra with real-rank zero is determined up to stable isomorphism by its ordered \( K_0 \)-group and its \( K_1 \)-group [11]. Thus we turn our attention in Section 5 to identifying rank-2 Bratteli diagrams whose C*-algebras have real-rank zero. Theorem 5.1 establishes a necessary and sufficient condition on Λ for \( C^*(Λ) \) to be simple. We then identify a large-permutation factorisations property which guarantees that projections in \( C^*(Λ) \) separate traces, and deduce from [2] that if Λ has large-permutation factorisations and is cofinal in the sense of [18], then \( C^*(Λ) \) is simple and has real-rank zero (Theorem 5.7).

In Section 6 we identify the pairs \((K_0, K_1)\) which can arise as the \( K \)-theory of the C*-algebra of a rank-2 Bratteli diagram, and identify among these the pairs which are achievable when \( C^*(Λ) \) is simple and has real-rank zero. We then construct for each irrational number \( θ \in (0, 1) \) a rank-2 Bratteli diagram \( Λ_θ \) with large-permutation factorisations such that the irrational rotation algebra \( A_θ \) is isomorphic to a full corner of \( C^*(Λ_θ) \), and for each infinite supernatural number \( m \) a rank-2 Bratteli diagram \( Λ(m) \) with large-permutation factorisations such that the Bunce-Deddens algebra of type \( m \) is isomorphic to a full corner of \( C^*(Λ(m)) \). These algebras are examples of simple 2-graph
$C^*$-algebras which are neither AF nor purely infinite, and show that the dichotomy of [19] fails for 2-graphs.

In the last two sections we consider rank-2 Bratteli diagrams in which all the red cycles have length 1. For such rank-2 Bratteli diagrams we show that the partial inclusions between approximating circle algebras are standard permutation mappings, and identify the associated permutations explicitly in terms of the factorisation property in $\Lambda$. We then consider arbitrary direct limits of circle algebras under such inclusions. We give a sufficient condition for such algebras to have real-rank zero and a related necessary condition. We describe the trace simplex in both cases. When each approximating algebra contains just one direct summand, we obtain a single necessary and sufficient condition for the limit algebra to have real-rank zero.

2. Preliminaries and notation

Our conventions regarding 2-graphs are largely those of [18]. By $\mathbb{N}^2$, we mean the semigroup $\{(n_1, n_2) \in \mathbb{Z}^2 : n_i \geq 0\}$; we write $e_1 = (1, 0)$, $e_2 = (0, 1)$ and 0 for the identity $(0, 0)$. We view $\mathbb{N}^2$ as a category with one object. We define a partial order on $\mathbb{N}^2$ by $m \leq n$ if and only if $m_1 \leq n_1$ and $m_2 \leq n_2$.

A 2-graph is a pair $(\Lambda, d)$ consisting of a countable category $\Lambda$ and a functor $d : \Lambda \to \mathbb{N}^2$ which satisfies the factorisation property: if $\lambda \in \Lambda$ and $d(\lambda) = m + n$ then there exist unique $\mu$ and $\nu$ in $\Lambda$ such that $d(\mu) = m$, $d(\nu) = n$ and $\lambda = \mu \nu$. We refer to the morphisms of $\Lambda$ as the paths in $\Lambda$; the degree $d(\lambda)$ is the rank-2 analogue of the length of the path $\lambda$, and we write $\Lambda^n := d^{-1}(n)$. We call the objects of $\Lambda$ vertices, the domain $s(\lambda)$ of $\lambda$ the source of $\lambda$, and the codomain $r(\lambda)$ the range of $\lambda$. We refer to the paths in $\Lambda^{e_1}$ as blue edges and those in $\Lambda^{e_2}$ as red edges.

The factorisation property applies with $d(\lambda) = 0 + d(\lambda) = d(\lambda) + 0$, and the uniqueness of factorisations then implies that $v \mapsto \text{id}_v$ is a bijection between the objects of $\Lambda$ and the set $\Lambda^0$ of paths of degree 0. We use this bijection to to identify the objects of $\Lambda$ with the paths $\Lambda^0$ of degree 0, and we view $r, s$ as maps from $\Lambda$ to $\Lambda^0$. We say that $\Lambda$ is row-finite if the set $\{\lambda \in \Lambda : r(\lambda) = v, d(\lambda) = n\}$ is finite for every vertex $v \in \Lambda^0$ and every degree $n \in \mathbb{N}^2$. A 2-graph $\Lambda$ is locally convex if, whenever $e$ is a blue edge and $f$ is a red edge with $r(e) = r(f)$, there exist a red edge $f'$ and a blue edge $e'$ such that $r(f') = s(e)$ and $r(e') = s(f)$.

For $\lambda \in \Lambda$ and $0 \leq m \leq n \leq d(\lambda)$, we write $\lambda(m, n)$ for the unique path in $\Lambda$ such that $\lambda = \lambda'\lambda(m, n)\lambda''$ where $d(\lambda') = m$, $d(\lambda(m, n)) = n - m$ and $d(\lambda'') = d(\lambda) - n$. We write $\lambda(n)$ for $\lambda(n, n) = s(\lambda(0, n))$.

For $E \subseteq \Lambda$ and $\lambda \in \Lambda$, we denote by $\lambda E$ the collection $\{\lambda \mu : \mu \in E, r(\mu) = s(\lambda)\}$ of paths which extend $\lambda$. Similarly $E\lambda := \{\mu \lambda : \mu \in E, s(\mu) = r(\lambda)\}$. In particular when $\lambda = v \in \Lambda^0$, $Ev = E \cap s^{-1}(v)$ and $vE = E \cap r^{-1}(v)$.

As in [24], we write $\Lambda^{\leq n} := \{\lambda \in \Lambda : d(\lambda) \leq n, \lambda \mu \in \lambda \Lambda \setminus \{\lambda\} \implies d(\lambda \mu) \leq n\}$.

The $C^*$-algebra $C^*(\Lambda)$ of a row-finite locally convex 2-graph $\Lambda$ is the universal algebra generated by a collection $\{s_\lambda : \lambda \in \Lambda\}$ of partial isometries (called a Cuntz-Krieger $\Lambda$-family) satisfying

\begin{itemize}
  \item[(CK1)] $\{s_v : v \in \Lambda^0\}$ is a collection of mutually orthogonal projections;
\end{itemize}
(CK2) \( s_\mu s_\nu = s_{\mu \nu} \) whenever \( s(\mu) = r(\nu) \);
(CK3) \( s_\mu^* s_\mu = s_{s(\mu)} \) for all \( \mu \); and
(CK4) \( s_v = \sum_{\lambda \in \Lambda} s_\lambda s_\lambda^* \) for all \( v \in \Lambda^0 \) and \( n \in \mathbb{N}^2 \).

Proposition 3.11 of [24] shows that (CK4) is equivalent to
\[
s_v = \sum_{e \in v \Lambda^1} s_e s_e^* \quad \text{for all} \quad v \in \Lambda^0 \quad \text{and} \quad i = 1, 2.
\]

There is a strongly continuous action \( \gamma : \mathbb{T}^2 \to \text{Aut}(C^*(\Lambda)) \) called the gauge action which satisfies \( \gamma(z)(s_\lambda) = z^{d(\lambda)} s_\lambda \) for all \( \lambda \), where \( z^n := z_1^{n_1} z_2^{n_2} \in \mathbb{T} \) for \( z \in \mathbb{T}^2 \) and \( n \in \mathbb{N}^2 \).

For \( i = 1, 2 \), the function \( f_i \) is the homomorphism \( f_i(n) = ne_i \) of \( \mathbb{N} \) into \( \mathbb{N}^2 \). As in [18], we write \( f_i^* \Lambda \) for the pullback
\[
f_i^* \Lambda := \{(\lambda, n) : n \in \mathbb{N}, \lambda \in \Lambda, f_i(n) = d(\lambda)\},
\]
which is a 1-graph with the same vertex set as \( \Lambda \). We call \( f_1^* \Lambda \) the blue graph and \( f_2^* \Lambda \) the red graph. In this paper, we identify \( f_i^* \Lambda \) with \( d^{-1}(f_i(\mathbb{N})) \subset \Lambda \).

A cycle in a \( k \)-graph is a path \( \lambda \) such that \( d(\lambda) \neq 0 \), \( r(\lambda) = s(\lambda) \) and \( \lambda(n) \neq s(\lambda) \) for \( 0 < n < d(\lambda) \). A loop is a cycle consisting of a single edge. We say that the cycle \( \lambda \) has an entrance if there exists \( n \leq d(\lambda) \) such that \( r(\lambda(0, n)) \) is nonempty. Likewise, \( \lambda \) is said to have an exit if there exists \( n \leq d(\lambda) \) such that \( \lambda^n s(\lambda) \setminus \{\lambda(d(\lambda) − n, d(\lambda))\} \) is nonempty. We say that the cycle \( \lambda \) is isolated if it has no entrances and no exits.

We say that a \( k \)-graph \( \Lambda \) is finite if \( \Lambda^n \) is finite for each \( n \). If \( \Lambda \) is row-finite, this is equivalent to the assumption that \( \Lambda^0 \) is finite.

3. Rank-2 graphs with \( \mathbb{AT} \) \( C^* \)-algebras

In this section we prove the following theorem which identifies a class of 2-graphs whose \( C^* \)-algebras are \( \mathbb{AT} \) algebras.

**Theorem 3.1.** Let \( (\Lambda, d) \) be a 2-graph such that
\[
(\Lambda) \text{ is row-finite, } f_1^* \Lambda \text{ contains no cycles, each vertex } v \in \Lambda^0 \text{ is the range of an isolated cycle } \lambda(v) \text{ in } f_2^* \Lambda.
\]
Then \( C^*(\Lambda) \) is an \( \mathbb{AT} \) algebra.

If \( \Lambda \) satisfies condition (3.1) then each vertex \( v \) lies on a unique isolated cycle \( \lambda(v) \) and hence \( v \) is the range of exactly one red edge and the source of exactly one red edge. If \( e \) is a blue edge there are unique red edges \( f, g \) with \( r(f) = r(e) \) and \( r(g) = s(e) \) and then the factorisation property implies that there is a unique blue edge \( e' \) such that \( eg = fe' \). Hence every 2-graph \( \Lambda \) which satisfies condition (3.1) is locally convex.

Figure illustrates the skeleton of a 2-graph satisfying condition (3.1); in this and all our other diagrams we draw the blue edges as solid lines and the red edges as dashed lines.

**Notation 3.2.** If \( \Lambda \) is a 2-graph, we write \( \mathcal{F} \) for the factorisation map defined on pairs \( (\rho, \tau) \) such that \( s(\rho) = r(\tau) \) by
\[
\mathcal{F}(\rho, \tau) := ((\rho \tau)(0, d(\tau)), (\rho \tau)(d(\tau), d(\rho \tau))).
\]
If \( \mathcal{F}(\rho, \tau) = (\tau', \rho') \), then we write \( \mathcal{F}_1(\rho, \tau) := \tau' \) and \( \mathcal{F}_2(\rho, \tau) := \rho' \). So: \( \mathcal{F}_1(\rho, \tau) \) has the same degree as \( \tau \) and the same range as \( \rho \); \( \mathcal{F}_2(\rho, \tau) \) has the same degree as \( \rho \) and the same range as \( \tau \); and \( \mathcal{F}_1(\rho, \tau) \mathcal{F}_2(\rho, \tau) = \rho \tau \).
Lemma 3.3. Let \((\Lambda, d)\) be a 2-graph which satisfies condition (3.1). Suppose that \(\lambda_1\) and \(\lambda_2\) are isolated cycles in \(f_2^* \Lambda\). Let \(V_1\) and \(V_2\) denote the vertices on \(\lambda_1\) and \(\lambda_2\) respectively.

(1) For \(\mu \in V_1(f_2^* \Lambda)\), the map \(F_1(\mu, \cdot) : s(\mu)(f_1^* \Lambda)V_2 \rightarrow r(\mu)(f_1^* \Lambda)V_2\) obtained from the factorisation map above is a degree-preserving bijection, and

(2) for \(\nu \in V_2(f_2^* \Lambda)\), the map \(F_2(\cdot, \nu) : V_1(f_1^* \Lambda)r(\nu) \rightarrow V_1(f_1^* \Lambda)s(\nu)\) obtained from the factorisation map above is also a degree-preserving bijection.

Proof. We just prove statement (1); statement (2) follows from a very similar argument.

The map is degree-preserving by definition. Since \(r(\mu \sigma) = r(\mu)\), the image of \(F_1(\mu, \cdot)\) is a subset of \(r(\mu)\). For \(\sigma \in s(\mu)(f_1^* \Lambda)V_2\), we have that \((\nu \sigma) = F_1(\nu, \sigma)F_2(\nu, \sigma)\) where \(F_2(\nu, \sigma) \in \Lambda^{d(\nu)}s(\sigma)\). Now \(s(\sigma)\) lies on the isolated cycle \(\lambda_2\) in \(f_2^* \Lambda\). Since \(F_2(\nu, \sigma) \in f_2^* \Lambda\), it follows that \(s(F_1(\nu, \sigma)) = r(F_2(\nu, \sigma)) \in V_2\) as well. Hence \(F_1(\nu, \sigma)\) belongs to \(r(\nu)(f_1^* \Lambda)V_2\).

To see that \(F_1(\nu, \cdot)\) is bijective, note that for \(\sigma' \in r(\nu)\Lambda V_2\), there is a unique path \(\nu'(\sigma') \in s(\sigma')\Lambda^{d(\nu)}\) because \(\lambda_2\) is isolated. Hence \(\sigma' \mapsto F_2(\sigma', \nu'(\sigma'))\) is an inverse for \(F_1(\nu, \cdot)\).

Notation 3.4. (1) Let \((\Lambda, d)\) be a 2-graph which satisfies condition (3.1). If \(e\) is a red edge and \(\mu\) is a red path, then \(\langle \mu, e \rangle\) is the number of occurrences of \(e\) in \(\mu\).

(2) Since lower case \(e\)'s already denote generators of \(\mathbb{N}^k\) and edges of \(k\)-graphs, we do not use them to denote matrix units. If \(I\) is an index set, we write \(\{\Theta(i, j) : i, j \in I\}\) for the canonical matrix units in \(M_I(\mathbb{C})\); we use \(\{\theta(i, j) : i, j \in I\}\) to denote a set of matrix units in some other \(C^*\)-algebra.

(3) We write \(z\) for the monomial \(z \mapsto z \in C(\mathbb{T})\), and \(z^n\) for \(z \mapsto z^n\).

Proposition 3.5. Let \((\Lambda, d)\) be a finite 2-graph which satisfies condition (3.1). Suppose that the set \(S\) of sources in \(f_1^* \Lambda\) are the vertices on a single isolated cycle in \(f_2^* \Lambda\). Let \(Y\) denote the collection \((f_1^* \Lambda)S\) of blue paths with source in \(S\). Fix an edge \(e_\alpha, e_\beta\) in \(S \Lambda e_2^* S\). Then there is an isomorphism \(\pi : C^*(\Lambda) \rightarrow M_Y(C(\mathbb{T}))\) such that for \(\alpha, \beta \in Y\) and \(\nu \in s(\alpha)\Lambda^{d(\nu)}s(\beta)\),

\[(3.2) \quad \pi(s_\alpha s_\nu s_\beta)(z) = z^{(\nu, e_{\alpha})}\Theta(\alpha, \beta).\]

The proof of the proposition is long, but not particularly difficult. The strategy is to identify a family of nonzero matrix units \(\{\theta(\alpha, \beta) : \alpha, \beta \in Y\}\) and a unitary \(U\) in \(C^*(\Lambda)\).
such that $U$ commutes with each $\theta(\alpha, \beta)$. This gives a homomorphism $\phi$ of $M_Y(\mathbb{C}) \otimes \mathbb{T}$ into $C^*(\Lambda)$. Since the matrix units are nonzero, we just have to show that $U$ has full spectrum to see that $\phi$ is injective. We then show that $\phi$ is also surjective, and that taking $\pi = \phi^{-1}$ gives an isomorphism satisfying (3.2).

We proceed in a series of lemmas. We begin with a simple technical lemma which we will use frequently.

**Lemma 3.6.** Let $(\Lambda, d)$ be a 2-graph which satisfies condition (3.1), and let $\mu, \nu$ be red paths in $\Lambda$.

1. If $r(\mu) \neq r(\nu)$ then $s^*_\mu s_\nu = 0$; otherwise either $\nu = \mu\mu'$ and $s^*_\mu s_\nu = s_\nu$ or $\mu = \nu\mu'$ and $s^*_\mu s_\nu = s^*_\nu$.
2. If $s(\mu) \neq s(\nu)$ then $s^*_\mu s^*_\nu = 0$; otherwise either $\mu = \nu\nu'$ and $s_\mu s^*_\nu = s_{\nu'}$ or $\nu = \nu'\mu$ and $s_{\mu'} s^*_\nu = s^*_{\nu'}$.

**Proof.** Relation (CK1) shows that $s^*_\mu s_\nu = 0$ when $r(\mu) \neq r(\nu)$ and that $s_\mu s^*_\nu = 0$ when $s(\mu) \neq s(\nu)$. Because $f_1^*\Lambda$ is a union of isolated cycles, we have either $\mu = \nu\mu'$ or $\nu = \nu'\mu$ when $r(\mu) = r(\nu)$, and either $\mu = \nu\nu'$ or $\nu = \nu'\mu$ when $s(\mu) = s(\nu)$. So (1) follows from (CK3), and (2) follows from (CK4) because $r(\mu)\Lambda^{\leq d(\nu)} = r(\mu)\Lambda^{d(\nu)} = \{\mu\}$ for all $\mu \in f_1^*\Lambda$.

**Lemma 3.7.** Suppose that $(\Lambda, d)$ is a finite 2-graph which satisfies condition (3.1). Let $S$ denote the collection of sources in $f_1^*\Lambda$, and let $Y := (f_1^*\Lambda)S$. Then

$$C^*(\Lambda) = \overline{\text{span}} \{s_\alpha s_\nu s^*_\beta, s_\alpha s^*_\nu s^*_\beta : \alpha, \beta \in Y, \nu \in S(f_2^*\Lambda)S\}.$$

**Proof.** By [24, Remark 3.8(1)],

$$C^*(\Lambda) = \overline{\text{span}} \{s_\rho s^*_\xi : \rho, \xi \in \Lambda, s(\rho) = s(\xi)\},$$

so it suffices to show that for all $\rho, \xi \in \Lambda$ with $s(\rho) = s(\xi)$, we can write $s_\rho s^*_\xi$ as a sum of elements of the form $s_\alpha s_\nu s^*_\beta$ or $s_\alpha s^*_\nu s^*_\beta$.

Fix $\rho, \xi \in \Lambda$ with $s(\rho) = s(\xi)$. Since $f_1^*\Lambda$ has no cycles, and $\Lambda^0$ is finite, there exists $N \in \mathbb{N}$ such that $\Lambda^{\leq N+1} = \emptyset$ for all $n \geq N$. Thus $\Lambda^{\leq N+1} = (f_1^*\Lambda)S = Y$. Hence (CK4) gives $s_\rho s^*_\xi = \sum_{s(\eta)Y} s_\rho s^*_\eta \xi$. For fixed $\alpha \in s(\rho)Y$, we factorise $\rho\alpha = \eta\mu$ and $\xi\alpha = \zeta\nu$ where $\eta, \zeta \in f_1^*\Lambda$ and $\mu, \nu \in f_2^*\Lambda$. Since $f_2^*\Lambda$ consists of isolated cycles, we must have $s(\eta), s(\zeta) \in S$, so $\eta, \zeta \in Y$, and $\mu, \nu \in S(f_2^*\Lambda)S$. We have $s(\mu) = s(\nu) = s(\rho\alpha) = s(\xi\alpha) = s(\nu) = s(\nu)$. Hence Lemma 3.6 shows that either $s_\rho s^*_\xi = s_\eta s_\mu s^*_\zeta$, or $s_\rho s^*_\xi = s_\eta s^*_\nu s^*_\zeta$, where $\mu, \nu \in S(f_2^*\Lambda)S$.

**Lemma 3.8.** Let $(\Lambda, d)$ be a finite 2-graph which satisfies condition (3.1). Suppose that the set of sources in $f_1^*\Lambda$ is the set of vertices on a single isolated cycle in $f_2^*\Lambda$. Let $Y := (f_1^*\Lambda)S$. Fix an edge $e_*$ in $S\Lambda^{\geq 2}S$, and for $\alpha, \beta \in Y$, let $\nu_0(\alpha, \beta)$ be the unique path connecting $s(\alpha)$ and $s(\beta)$ (in either direction) such that $\langle \nu_0(\alpha, \beta), e_* \rangle = 0$. Then the elements

$$\theta(\alpha, \beta) := \begin{cases} s_\alpha s_{\nu_0(\alpha, \beta)} s^*_\beta & \text{if } s(\nu_0(\alpha, \beta)) = s(\beta) \\ s_\alpha s^*_{\nu_0(\alpha, \beta)} s^*_\beta & \text{if } s(\nu_0(\alpha, \beta)) = s(\alpha) \end{cases}$$

form a collection of nonzero matrix units in $C^*(\Lambda)$. 

Hence $\sigma$ Let Lemma 3.10. commute with the unitary $S$ that the set $\begin{align*} & \text{begin at sources in } \theta \\ & \text{We need only show that } s_\beta s_\eta = \delta_{\beta,\eta} s_{s(\beta)} \text{. So it suffices to show that} \\ & \theta(\alpha, \beta) \theta(\beta, \zeta) = s_\alpha t_1 s_\beta s_\eta s_\zeta = s_\alpha t_2 s_\eta s_\zeta \text{ where } t_1 \in \{s_{\nu_0(\alpha, \beta), s_{\nu_0(\alpha, \beta)}}\} \text{ and } t_2 \in \{s_{\nu_0(\beta, \zeta), s_{\nu_0(\beta, \zeta)}}\}. \text{ Hence there are four cases to consider. We will deal with two of them; the other two arguments are very similar.} \\ & \text{If } t_1 = s_{\nu_0(\alpha, \beta)} \text{ and } t_2 = s_{\nu_0(\beta, \zeta)}, \text{ then } t_1 t_2 = s_{\nu_0(\alpha, \beta)\nu_0(\beta, \zeta)}. \text{ Since neither } \nu_0(\alpha, \beta) \text{ nor } \nu_0(\beta, \zeta) \text{ contains an instance of } e_\ast, \text{ neither does } \nu = \nu_0(\alpha, \beta)\nu_0(\beta, \zeta). \text{ Hence } \nu = \nu_0(\alpha, \zeta) \text{ by definition, so } \theta(\alpha, \beta) \theta(\beta, \zeta) = \theta(\alpha, \zeta). \\ & \text{If } t_1 = s_{\nu_0(\alpha, \beta)} \text{ and } t_2 = s_{\nu_0(\beta, \zeta)}, \text{ then Lemma 3.6 shows that } t_1 t_2 \text{ has the form } s_\nu \text{ or } s^*_\nu \text{ depending on which of } \nu_0(\alpha, \beta) \text{ and } \nu_0(\beta, \zeta) \text{ is longer. In either case, } \nu \text{ is a path joining } s(\alpha) \text{ and } s(\zeta), \text{ and since it is a sub-path of one of } \nu_0(\alpha, \beta) \text{ and } \nu_0(\beta, \zeta), \text{ neither of which contains an instance of } e_\ast, \text{ we once again have } \nu = \nu_0(\alpha, \zeta). \quad \square 
\end{align*}$

**Lemma 3.9.** Let $(\Lambda, d)$ be a finite 2-graph which satisfies condition (3.1). Suppose that the set $S$ of sources in $f_0^2 \Lambda$ is the set of vertices on a single isolated cycle in $f_1^2 \Lambda$. Let $Y := (f_0^2 \Lambda) S$, and for $\alpha \in Y$, let $\lambda(\alpha)$ be the unique isolated cycle in $s(\alpha)(f_0^2 \Lambda)$. Let $U := \sum_{\alpha \in Y} s_\alpha s_{\lambda(\alpha)} s^*_\alpha$. Then $U$ is a unitary in $C^*(\Lambda)$ and the spectrum of $U$ is $\mathbb{T}$.

**Proof.** For $\alpha, \beta \in Y$, we have $s^*_\alpha s_\beta = \delta_{\alpha, \beta} s_{s(\alpha)}$, so

$$UU^* = \sum_{\alpha, \beta \in Y} s_\alpha s_{\lambda(\alpha)} s^*_\alpha s_\beta s^*_\lambda s^*_\beta = \sum_{\alpha \in Y} s_\alpha s_{\lambda(\alpha)} s^*_\lambda s^*_\alpha = \sum_{\alpha \in Y} s_\alpha s^*_\alpha$$

by Lemma 3.6. Since $\Lambda$ is finite, there exists $N \in \mathbb{N}$ such that $\Lambda^{\leq N+1} = Y$, and so it follows from the calculation above and (CK4) that $UU^* = \sum_{\nu \in \Lambda^0} s_\nu = 1_{C^*(\Lambda)}$.

A similar calculation establishes that $U^* U = 1_{C^*(\Lambda)}$. It remains to show that $U$ has spectrum $\mathbb{T}$. For this, notice that $d(\lambda(\alpha)) = |S| e_2$ for all $\alpha \in Y$. Hence the gauge action satisfies $\gamma_{1,y}(U) = y S |U|$ for $y \in \mathbb{T}$. Fix $z \in \sigma(U)$ and $w \in \mathbb{T}$, and choose $y \in \mathbb{T}$ such that $y |S| = z w$. We have

$$z \in \sigma(U) \implies U - z 1_{C^*(\Lambda)} \not\in C^*(\Lambda)^{-1} \implies \gamma_{1,y}(U - z 1_{C^*(\Lambda)}) \not\in C^*(\Lambda)^{-1} \implies y |S| U - z 1_{C^*(\Lambda)} \not\in C^*(\Lambda)^{-1} \implies z (\pi U - 1_{C^*(\Lambda)}) \not\in C^*(\Lambda)^{-1} \implies w \in \sigma(U).$$

Hence $\sigma(U) = \mathbb{T}$. \quad \square 

**Lemma 3.10.** Let $(\Lambda, d)$ be a finite 2-graph which satisfies condition (3.1), and suppose that the set $S$ of sources in $f_0^2 \Lambda$ is the set of vertices on a single isolated cycle in $f_1^2 \Lambda$. Let $Y := (f_0^2 \Lambda) S$. Fix an edge $e_\ast$ in $S \Lambda^e S$. Then the matrix units $\theta(\alpha, \beta)$ of Lemma 3.8 commute with the unitary $U$ of Lemma 3.9.
Proof. Fix $\alpha, \beta \in Y$ and $n \in \mathbb{N}$. Let $\nu_n(\alpha, \beta)$ be the unique path in $s(\alpha)(f_1^*\Lambda)s(\beta)$ such that $\langle \nu_n(\alpha, \beta), e_s \rangle = n$. Using (CK2) and Lemma 3.6 it is easy to check that
\begin{equation}
U^n\theta(\alpha, \beta) = s_\alpha s_{\nu_n(\alpha, \beta)}s_\beta^* = \theta(\alpha, \beta)U^n.
\end{equation}
Taking $n = 1$ proves the lemma. \hfill \Box

Proof of Proposition 3.10. Define $\theta(\alpha, \beta)$ and $U$ as in Lemmas 3.8 and 3.9. The universal properties of $M_Y(\mathbb{C})$ and of $C(\mathbb{T}) = C^*(\mathbb{Z})$ ensure that there are homomorphisms $\phi_M : M_Y(\mathbb{C}) \to C^*(\Lambda)$ and $\phi_T : C(\mathbb{T}) \to C^*(\Lambda)$ such that $\phi_M(\Theta(\alpha, \beta)) = \theta(\alpha, \beta)$ and $\phi_T(z) = U$. We know $\phi_M$ is injective because the $\theta(\alpha, \beta)$ are all nonzero by Lemma 3.8. We know $\phi_T$ is injective because $U$ has full spectrum by Lemma 3.9. Since $U$ commutes with the $\theta(\alpha, \beta)$ by Lemma 3.11 there is a well-defined homomorphism $\phi = \phi_M \otimes \phi_T : M_Y(\mathbb{C}) \otimes C(\mathbb{T}) \to C^*(\Lambda)$ which satisfies $\phi(\Theta(\alpha, \beta) \otimes z^n) = \theta(\alpha, \beta)U$. Moreover, $\phi$ is injective because both $\phi_M$ and $\phi_T$ are injective.

We claim that $\phi$ is also surjective. By Lemma 3.7 we need only show that if $\alpha, \beta \in Y$ and $\mu \in s(\alpha)(f_2^*\Lambda)s(\beta)$, then $s_\alpha s_\mu s_\beta^*$ belongs to the image of $\phi$: taking adjoints then shows that $s_\alpha s_\mu s_\beta^*$ also belongs to the image of $\phi$. A straightforward calculation shows that $s_\alpha s_\mu s_\beta^* = U^{(\mu, e_s)}(\alpha, \beta) = \phi(\Theta(\alpha, \beta) \otimes z^{(\mu, e_s)})$.

Let $\pi := \phi^{-1}$. Since $\pi(\theta(\alpha, \beta)) = \Theta(\alpha, \beta)$ and $\pi(U) = z$, equation (3.3) implies that $\pi$ satisfies (3.2). \hfill \Box

Proposition 3.11. Let $(\Lambda, d)$ be a finite 2-graph satisfying condition (3.1). Let $S$ be the set of sources of $f_1^*\Lambda$, and write $S = S_1 \sqcup \cdots \sqcup S_n$ where each $S_j$ is the set of vertices on one of the isolated cycles in $f_2^*\Lambda$. For $1 \leq j \leq n$, let $\Lambda_j := \{ \lambda \in \Lambda : s(\lambda)\Lambda S_j \neq \emptyset \}$, and let $d_j$ denote the restriction of the degree map $d$ to $\Lambda_j$.

1. Each $(\Lambda_j, d_j)$ is a 2-graph which satisfies condition (3.1), and $S_j = S \cap \Lambda_j$ is precisely the set of sources in $f_1^*\Lambda_j$.

2. For $1 \leq j \leq n$, let $\{ s_{\rho, \lambda} : \rho \in \Lambda_j \}$ denote the universal generating Cuntz-Krieger $\Lambda_j$-family. There is an isomorphism of $C^*(\Lambda)$ onto $\bigoplus_{j=1}^n C^*(\Lambda_j)$ which carries $s_\alpha s_\mu s_\beta^*$ to $(0, \ldots, 0, s_{\alpha,\lambda} s_{\mu,\rho} s_{\beta,\sigma}^*, 0, \ldots, 0)$ for $\alpha, \beta \in Y_j := (f_1^*\Lambda_j)S_j$ and $\mu \in s(\alpha)(f_2^*\Lambda_j)s(\beta)$.

Proof. (1) Fix $1 \leq j \leq n$. To see that $\Lambda_j$ is a category, note that for $\rho \in \Lambda$, we have $\rho \in \Lambda_j$ if and only if $s(\rho) \in \Lambda_j$. Hence $\xi \in \Lambda_j$ implies $\rho \xi \in \Lambda_j$.

To check the factorisation property, suppose that $\rho \in \Lambda_j$ and $d_j(\rho) = p + q$. The factorisation property for $\Lambda$ ensures that there is a unique factorisation $\rho = \rho'\rho''$ where $d(\rho') = p$ and $d(\rho'') = q$, so we need only show that $\rho', \rho'' \in \Lambda_j$. Since $\rho \in \Lambda_j$, there exists a path $\xi \in s(\rho)\Lambda S_j = s(\rho'')\Lambda S_j$, and it follows that $\rho'' \in \Lambda_j$. Moreover, $\rho'\xi \in s(\rho')\Lambda S_j$ giving $\rho' \in \Lambda_j$ as well.

Since $\Lambda_j$ is a subgraph of $\Lambda$ it is row-finite, and $f_1^*\Lambda_j$ is cycle-free. For a given isolated cycle $\lambda$ in $f_2^*\Lambda$, one of the vertices on $\lambda$ lies in $\Lambda_j$ if and only if they all do, and in this case all the edges in $\lambda$ belong to $\Lambda_j$ as well. Thus each vertex of $\Lambda_j$ lies on an isolated cycle in $f_2^*\Lambda_j$. So $\Lambda_j$ satisfies condition (3.1).

Let $\nu \in S_j$ and fix $\rho \in v\Lambda$. Write $\rho = \sigma \mu$ where $\sigma \in f_1^*\Lambda$ and $\mu \in f_2^*\Lambda$. Since $S_j \subset S$, we must have $d(\sigma) = 0$. But now $\mu \in v(f_2^*\Lambda) \subset S(f_2^*\Lambda)$. By assumption, $S(f_2^*\Lambda) = \bigcup_{j=1}^n S_j(f_2^*\Lambda)S_j$, so $\rho \in S_j\Lambda S_j$, and $s(\rho) \in S_j$. Since the $S_j$ are disjoint, $S_j\Lambda S_l = \emptyset$ for $j \neq l$, and it follows that $S_j = S \cap \Lambda_j$. 
Finally, to see that the sources in \(f_1^*\Lambda_j\) are precisely \(S \cap \Lambda_j\), note first that elements of \(S \cap \Lambda_j\) are clearly sources in \(f_1^*\Lambda_j\). For the reverse inclusion, let \(v\) be a source in \(f_1^*\Lambda_j\), so \(v(f_1^*\Lambda_j) = \{v\}\). Since \(v \in \Lambda_j\), we have \(v\Lambda S_j \neq \emptyset\), say \(v \in v\Lambda S_j\). Factorise \(\rho = \sigma \mu\) where \(\sigma \in f_1^*\Lambda\) and \(\mu \in f_2^*\Lambda\). Since \(\Lambda\) satisfies condition (3.4), we have \(S(f_2^*\Lambda) = (f_2^*\Lambda)S\). We have \(s(\mu) \in S_j\) by choice of \(\rho\), and we therefore have \(r(\mu) \in S_j\). But \(r(\mu) = s(\sigma)\), so 

\[
\sigma \in (f_1^*\Lambda)S_j = f_1^*\Lambda_j.
\]

But \(v\) was a source in \(f_1^*\Lambda_j\), giving \(v = r(\sigma) = s(\sigma) \in S_j\).

(2) Define operators \(\{t_\rho : \rho \in \Lambda\} \in \bigoplus_{\rho \in \Lambda}^n C^*(\Lambda_j)\) by \(t_\rho := \bigoplus_{\{j: \rho \in \Lambda_j\}} s_{j,\rho}\). Because each \(\{s_{j,\rho} : \rho \in \Lambda_j\}\) is a Cuntz-Krieger family, \(\{t_\rho : v \in \Lambda^0\}\) is a collection of mutually orthogonal projections, so \(\{t_\rho : \rho \in \Lambda\}\) satisfies (CK1).

If \(\rho, \xi \in \Lambda\) satisfy \(s(\rho) = r(\xi)\), then

\[
(3.4) \quad t_\rho t_\xi = \left( \bigoplus_{\{j: \rho \in \Lambda_j\}} s_{j,\rho} \right) \left( \bigoplus_{\{l: \xi \in \Lambda_l\}} s_{l,\xi} \right) = \bigoplus_{\{j: \rho, \xi \in \Lambda_j\}} s_{j,\rho} s_{j,\xi} = \bigoplus_{\{j: \rho, \xi \in \Lambda_j\}} s_{j,\rho,\xi}.
\]

Since \(\rho, \xi \in \Lambda_j\) and only if \(\xi \in \Lambda_j\) and since \(\xi \in \Lambda_j \implies \rho \in \Lambda_j\), the right-hand side of (3.4) is equal to \(t_{\rho,\xi}\). Hence \(\{t_\rho : \rho \in \Lambda\}\) satisfies (CK2).

For \(\rho, \xi \in \Lambda\), we have

\[
t_\rho^* t_\xi = \left( \bigoplus_{\{j: \rho \in \Lambda_j\}} s_{j,\rho}^* \right) \left( \bigoplus_{\{l: \rho \in \Lambda_l\}} s_{l,\rho} \right) = \bigoplus_{\{j: \rho, \xi \in \Lambda_j\}} s_{j,\rho}^* s_{j,\rho} = \bigoplus_{\{j: \rho, \xi \in \Lambda_j\}} s_{j,\rho,\xi}.
\]

Since \(\rho \in \Lambda_j\) if and only if \(s(\rho) \in \Lambda_j\), \(\{t_\rho : \rho \in \Lambda\}\) satisfies (CK3).

Finally, fix \(v \in \Lambda^0\). To establish that the \(\{t_\rho : \rho \in \Lambda\}\) satisfy (CK4), we need only show that \(t_v = \sum_{e \in v\Lambda^e} t_e t_e^*\) for \(i = 1, 2\). For \(i = 2\), this is easy as \(v\Lambda^{e_2}\) has precisely one element \(f\), and \(f \in \Lambda^j\) if and only if \(v \in \Lambda_j\). Hence

\[
t_f^* t_f = \bigoplus_{\{j: f \in \Lambda_j\}} s_{j,f}^* s_{j,f} = \bigoplus_{\{j: f \in \Lambda_j\}} s_{j,f} r(f) = t_v.
\]

Now consider \(i = 1\). Note that for \(v \in \Lambda^0\) and \(1 \leq j \leq n\), we have \(v \in \Lambda_j\) if and only if there exists a blue edge \(e \in v\Lambda^{e_1}\) such that \(e \in \Lambda_j\). Using this to reverse the order of summation in the third line below, we calculate:

\[
v = \bigoplus_{\{j: v \in \Lambda_j\}} s_{j,v} = \bigoplus_{\{j: v \in \Lambda_j\}} \left( \sum_{e \in v\Lambda^e} s_{j,e} s_{j,e}^* \right) = \sum_{e \in v\Lambda^{e_1}} \left( \bigoplus_{\{j: e \in \Lambda_j\}} s_{j,e} s_{j,e}^* \right) = \sum_{e \in v\Lambda^{e_1}} t_e t_e^*.
\]

and so \(\{t_\rho : \rho \in \Lambda\}\) satisfies (CK4), and hence is a Cuntz-Krieger \(\Lambda\)-family.

The universal property of \(C^*(\Lambda)\) gives a homomorphism \(\psi_t : C^*(\Lambda) \to \bigoplus_{j=1}^n C^*(\Lambda_j)\) such that \(\psi_t(s_{j,\rho}) = t_\rho\) for all \(\rho \in \Lambda\). We claim that \(\psi_t\) is bijective. To see that \(\psi_t\) is injective, let \(\gamma\) be the gauge action on \(C^*(\Lambda)\), and let \(\bigoplus_{j=1}^n \gamma_j\) be the direct sum of the gauge-actions on the \(C^*(\Lambda_j)\). Since \(d_j(\rho) = d(\rho)\) whenever \(\rho \in \Lambda_j\), it is easy to see that \(\psi_t \circ \gamma_z = \left( \bigoplus_{j=1}^n \gamma_j \right)_z \circ \psi_t\). Moreover, each \(\rho \in \Lambda\) belongs to at least one \(\Lambda_j\), and hence each \(t_\rho\) is nonzero. It now follows from the gauge-invariant uniqueness theorem [21 Theorem 4.1] that \(\psi_t\) is injective.

Finally, we must show that \(\psi_t\) is surjective. We just need to show that if \(\rho \in \Lambda_j\) then \(s_{j,\rho}\) belongs to the image of \(\psi_t\). For this, note that if \(\rho \in \Lambda_j\) satisfies \(s(\rho) \in S_j\), then we must have \(s(\rho)\Lambda S_l = \emptyset\) for \(j \neq l\). It follows that for such \(\rho\), we have \(s_{j,\rho} = t_\rho\). Now let
satisfies the hypotheses of Proposition 3.5. By Proposition 3.5, we then have

\[ f \]

the set of sources of \( Y \). By Corollary 3.12, \( \sum_{\alpha \in s(\rho)} Y_j \) t_{\rho a}^* = \psi_t(\sum_{\alpha \in s(\rho)} Y_j \ s_{\rho a}^*); belongs to the image of \( \psi_t \).

\[ \square \]

**Corollary 3.12.** Let \( (\Lambda, d) \) be a finite 2-graph which satisfies condition \( (3.1) \). Let \( S \) be the set of sources of \( f_1^* \), and write \( S = S_1 \sqcup \cdots \sqcup S_n \) where each \( S_j \) is the set of vertices on one of the isolated cycles in \( f_1^* \). For each \( j \), let \( Y_j := (f_1^* S_j) \). Then

\[ C^*(\Lambda) \cong \bigoplus_{j=1}^n M_{Y_j}(C(\mathbb{T})). \]

**Proof.** Proposition 3.11(2) gives \( C^*(\Lambda) \cong \bigoplus_{j=1}^n C^*(\Lambda_j) \). By Proposition 3.11(1), each \( \Lambda_j \) satisfies the hypotheses of Proposition 3.5. By Proposition 3.5 we then have \( C^*(\Lambda_j) \cong M_{Y_j}(C(\mathbb{T})) \) for each \( i \).

\[ \square \]

**Proof of Theorem 3.7.** By Proposition 3.2.3, it suffices to show that for every finite collection \( a_1, \ldots, a_n \) of elements of \( C^*(\Lambda) \), and every \( \varepsilon > 0 \) there exists a sub \( C^* \)-algebra \( B \subset C^*(\Lambda) \) and elements \( b_1, \ldots, b_n \in B \) such that \( B \cong \bigoplus_{i=1}^n M_{m_i}(C(\mathbb{T})) \) for some \( m_1, \ldots, m_n \in \mathbb{N} \), and such that \( \|a_i - b_i\| \leq \varepsilon \) for \( 1 \leq i \leq n \).

Since \( C^*(\Lambda) = \text{span} \{s_\rho s_\xi^*: \rho, \xi \in \Lambda\} \), it therefore suffices to show that for every finite collection \( F \) of paths in \( \Lambda \), there is a sub \( C^* \)-algebra \( B \subset C^*(\Lambda) \) such that \( B \cong \bigoplus_{i=1}^n M_{m_i}(C(\mathbb{T})) \) for some \( m_1, \ldots, m_n \in \mathbb{N} \), and such that \( B \) contains \( \{s_\rho s_\xi^*: \rho, \xi \in F\} \).

Our argument is based on the corresponding argument that the Cuntz-Krieger algebra of a directed graph with no cycles is AF in [10, Theorem 2.4].

Fix a finite set \( F \subset \Lambda \). Build a set \( G \subset \Lambda^{e_1} \) of blue edges as follows. First, let \( G_1 = \{\xi(n - e_1, n): \xi \in F, e_1 \leq n \leq d(\xi)\} \) be the collection of all blue edges which occur as segments of paths in \( F \). Then \( G_1 \) is finite because \( F \) is. Next, obtain \( G_2 \) by adding to \( G_1 \) all blue edges \( e \) such that \( r(e) = s(f) \) for some \( f \in G_1 \). So \( G_2 \) has the property that if \( e \in G_2 \), then either \( s(e) \Lambda^{e_1} \subset G_2 \) or \( s(e) \Lambda^{e_1} \cap G_2 = \emptyset \). Moreover \( G_2 \) is finite because \( \Lambda \) is row-finite. Finally, let \( G \) be the collection of all blue edges obtained by applying one of the bijections \( F_1(\mu, \cdot) \) of Lemma 3.3 to an element of \( G_2 \); that is \( G = \{F_1(\mu, e): e \in G_2, \mu \in (f_2^* \Lambda) r(e)\} \). Then \( G \) is finite because each isolated cycle has only finitely many vertices and \( \Lambda \) is row-finite.

Let \( \Gamma \) be the subset of \( \Lambda \) consisting of all vertices which are either the source or the range of an element of \( G \) together with all paths of the form \( \sigma \mu \) where \( \sigma \in f_1^* \Lambda \) is a concatenation of edges from \( \Gamma \) (that is, \( \sigma(n, n + e_1) \in G \) for all \( n \leq d(\sigma) - e_1 \)), and \( \mu \) is an element of \( s(\sigma)(f_2^* \Lambda) \). By construction, for each isolated cycle \( \lambda \) in \( f_2^* \Lambda \), any one of the vertices on \( \lambda \) is the source of an edge in \( G \) if and only if they all are. It follows that \( \Gamma \) is a category because it contains all concatenations of its elements by construction. Moreover, \( \Gamma \) satisfies the factorisation property by the construction of \( G \) from \( G_2 \); so \( \Gamma \) is a sub 2-graph of \( \Lambda \).

Since \( G \) is finite, \( \Gamma^0 \) is finite. By construction of \( G_2 \), for each isolated cycle \( \lambda \) in \( f_2^* \Lambda \), whose vertices are the sources of edges in \( G_2 \), and for each vertex \( v \) on \( \Lambda \), either \( v \Lambda^{e_1} \subset G \) or \( v \Lambda^{e_1} \cap G = \emptyset \). It follows that the Cuntz-Krieger relations for \( \Gamma \) are the same as those for \( \Lambda \), so there is a homomorphism \( \pi: C^*(\Gamma) \to C^*(\Lambda) \) such that \( \pi(s_\Gamma, \rho) = s_\Lambda, \rho \) for all \( \rho \in \Gamma \), where \( \{s_\Gamma, \rho: \rho \in \Gamma\} \), and \( \{s_\Lambda, \rho: \rho \in \Lambda\} \) are the universal generating Cuntz-Krieger families. The \( s_\Lambda, \rho \) are automatically nonzero and \( \pi \) clearly
implies that the structure of $C^*(\Gamma)$ intertwines the gauge actions on $C^*(\Lambda)$, so $\pi$ is an isomorphism of $C^*(\Gamma)$ onto $C^*(\{s_{\Lambda,\rho} : \rho \in \Gamma\}) \subset C^*(\Lambda)$.

But $\Gamma$ satisfies the hypotheses of Proposition 3.12 by construction, so $C^*(\Gamma) \cong \bigoplus_{f=1}^{|\Sigma|} M_f(C(\mathbb{T}))$. Hence taking $B := C^*(\{s_{\Lambda,\rho} : \rho \in \Gamma\})$ gives the required circle algebra in $C^*(\Lambda)$.

\section{Rank-2 Bratteli diagrams and their $C^*$-algebras}

\textbf{Definition 4.1.} A rank-2 Bratteli diagram of depth $N \in \mathbb{N} \cup \{\infty\}$ is a row-finite 2-graph $(\Lambda, d)$ such that $\Lambda^0$ is a disjoint union $\bigcup_{n=0}^{N} V_n$ of nonempty finite sets which satisfy

1. for every blue edge $e \in \Lambda^e_1$, there exists $n$ such that $r(e) \in V_n$ and $s(e) \in V_{n+1}$;

2. all vertices which are sinks in $f_n^* \Lambda$ belong to $V_0$, and all vertices which are sources in $f_n^* \Lambda$ belong to $V_N$ (where this is taken to mean that $f_n^* \Lambda$ has no sources if $N = \infty$); and

3. every $v$ in $\Lambda^0$ lies on an isolated cycle in $f_2^* \Lambda$, and for each red edge $f \in \Lambda^e_2$, there exists $n$ such that $r(f), s(f) \in V_n$.

Conditions (1) and (2) say that the blue graph $f_1^* \Lambda$ is the path category of a Bratteli diagram. Condition (3) says that each $V_n$ is itself a disjoint union $\bigcup_{i=1}^{c_n} V_{n,i}$ where each $V_{n,i}$ consists of the vertices on an isolated red cycle.

Every rank-2 Bratteli diagram $\Lambda$ satisfies condition (3), and hence Theorem 3.1 implies that $C^*(\Lambda)$ is an AT algebra. The inductive structure will give us an inductive limit decomposition which we use to obtain a very detailed description of the internal structure of $C^*(\Lambda)$ including $K$-invariants, ideal structure and real rank. To describe the $K$-invariants, we first need a technical lemma.

\textbf{Lemma 4.2.} Let $(\Lambda, d)$ be a rank-2 Bratteli diagram of depth $N$. Decompose $\Lambda^0 = \bigcup_{n=1}^{N} \bigcup_{j=1}^{c_n} V_{n,j}$ as above. For $0 \leq n < N$, $1 \leq j \leq c_n$ and $1 \leq i \leq c_{n+1}$

1. the sets $v \Lambda^e_1 V_{n+1,i}$, $v \in V_{n,j}$ have the same cardinality $A_n(i,j)$;

2. the sets $V_{n,j} \Lambda^e_2 w$, $w \in V_{n+1,j}$ have the same cardinality $B_n(i,j)$; and

3. the integers $A_n(i,j)$ and $B_n(i,j)$ satisfy

\begin{equation}
A_n(i,j) \mid V_{n,j} = |V_{n,j} \Lambda^e_1 V_{n+1,i}| = |V_{n+1,i}| B_n(i,j).
\end{equation}

The resulting matrices $A_n, B_n \in M_{c_n+1, c_{n+1}}(\mathbb{Z}_+)$ have no zero rows or columns. For $0 < n \leq N$, let $T_n \in M_{c_n}(\mathbb{Z}_+)$ be the diagonal matrix $T_n(j,j) = |V_{n,j}|$. Then $A_n T_n = T_{n+1} B_n$ for $0 \leq n < N$.

\textbf{Proof.} For statement (1), fix two vertices $v, w \in V_{n,j}$. Let $\mu$ be the segment of the isolated cycle round $V_{n,j}$ from $v$ to $w$. Lemma 3.1(1) implies that the factorisation map $F_1(\mu, \cdot)$ restricts to a bijection between $v \Lambda^e_1 V_{n+1,i}$ and $w \Lambda^e_1 V_{n+1,i}$. Statement (2) follows in a similar way from Lemma 3.3(2).

Parts (1) and (2) now show that $A_n(i,j) \mid V_{n,j}$ and $|V_{n+1,i}| B_n(i,j)$ are each equal to the number $|V_{n,j} \Lambda^e_1 V_{n+1,i}|$ of blue edges with source in $V_{n+1,i}$ and range in $V_{n,j}$. This establishes (4.1).

Equation (4.1) shows that $A_n(i,j) = 0$ if and only if $B_n(i,j) = 0$. By (1) and (2), the sum of the entries of the $i$th row of $A_n$ is equal to $|\Lambda^e_1 w|$ for any $w \in V_{n+1,i}$ and the sum of the entries of the $j$th column is $|v \Lambda^e_1|$ for any $v \in V_{n,j}$. It follows from Definition 4.1(2) that $A_n$, and hence also $B_n$, has no zero rows or columns.
The induced map $T$.

Proof of Theorem 4.3(3). Theorem 4.3 follows from statement (2).

Let $\Lambda$ be a rank-2 Bratteli diagram. We refer to the integers $c_n$ together with the matrices $A_n, B_n$ and $T_n$ arising from Lemma 4.2 as the data associated to $\Lambda$, and say that $\Lambda$ is a rank-2 Bratteli diagram with data $c_n, A_n, B_n, T_n$.

**Theorem 4.3.** Suppose that $(\Lambda, d)$ is a rank-2 Bratteli diagram of infinite depth with data $c_n, A_n, B_n, T_n$. Then

1. $C^*(\Lambda)$ is an $A_\infty$ algebra;
2. $K_0(C^*(\Lambda))$ is order-isomorphic to $\varprojlim(Z^{c_n}, A_n)$ and there is a group isomorphism of $K_1(C^*(\Lambda))$ onto $\varprojlim(Z^{c_n}, B_n)$;
3. $K_1(C^*(\Lambda))$ is isomorphic to a subgroup $H$ of $K_0(C^*(\Lambda))$ such that the quotient group $K_0(C^*(\Lambda))/H$ has rank zero as an abelian group;
4. the map $I \overset{\sim}{\longrightarrow} \langle [s_v] \mid s_v \in I \rangle \subset K_0(C^*(\Lambda))$ is an isomorphism of the lattice of gauge-invariant ideals of $C^*(\Lambda)$ onto the lattice of order-ideals of $K_0(C^*(\Lambda))$.

Theorem 4.3(1) follows from Theorem 3.1. We will show next that statement (3) of Theorem 4.3 follows from statement (2).

**Proof of Theorem 4.3(3).** Suppose for now that Theorem 4.3(2) holds. By Lemma 4.2 we have the following commuting diagram.

\[
\begin{array}{ccccccccc}
\cdots & \longrightarrow & Z^{c_n} & \overset{A_{\infty,n}}{\longrightarrow} & Z^{c_{n+1}} & \overset{T_n}{\longrightarrow} & Z^{c_{n+1}} & \overset{T_{n+1}}{\longrightarrow} & \cdots & \longrightarrow & \lim(Z^{c_n}, A_n) \cong K_0(C^*(\Lambda)) \\
\cdots & \longrightarrow & Z^{c_n} & \overset{B_{\infty,n}}{\longrightarrow} & Z^{c_{n+1}} & \overset{T_n}{\longrightarrow} & Z^{c_{n+1}} & \overset{T_{n+1}}{\longrightarrow} & \cdots & \longrightarrow & \lim(Z^{c_n}, B_n) \cong K_1(C^*(\Lambda))
\end{array}
\]

The induced map $T_\infty$ is injective because each $T_n$ is.

Let $H = T_\infty(K_1(C^*(\Lambda)))$. We must show that every element of $K_0(C^*(\Lambda))/H$ has finite order. Fix $g \in K_0(C^*(\Lambda))$, and fix $n \in \mathbb{N}$ and $m \in Z^{c_n}$ for which $g = A_{\infty,n}(m)$. Let $t \in \mathbb{N}$ be the least common multiple of the diagonal entries of $T_n$. For each $j$, $(tm)_j$ is divisible by $T_n(j,j)$, and it follows that $tm \in T_nZ^{c_n}$, say $tm = T_n p$. Now $tg = tA_{\infty,n}(m) = A_{\infty,n}(tm) = A_{\infty,n} \circ T_n(p) = T_\infty \circ B_{\infty,n}(p) \in H$. It follows that the order of $[g]$ in $K_0(C^*(\Lambda))/H$ is at most $t$. Since $g \in K_0(C^*(\Lambda))$ was arbitrary, it follows that every element of $K_0(C^*(\Lambda))/H$ has finite order as required.

Next we prove Theorem 4.3(2). To do so, we need some technical results.

**Lemma 4.4.** Let $(\Lambda, d)$ be a rank-2 Bratteli diagram of depth $N$. Let $X := V_0f_1^*\Lambda V_N$. Then $X = \Lambda^{N_{e_1}} = V_0\Lambda^{\leq N_{e_1}}$. The projection $P := \sum_{v \in V_0} s_v$ is full in $C^*(\Lambda)$, and is equal to $\sum_{a \in X} s_{a^*} s_a^*$.

**Proof.** That $X$ is equal to $\Lambda^{N_{e_1}}$ follows from property (1) of rank-2 Bratteli diagrams, and that this is also equal to $V_0\Lambda^{\leq N_{e_1}}$ follows from property (2). To see that $P$ is full, fix $\xi \in \Lambda$. By Definition 4.1(2), there exists $a \in V_0\Lambda\xi$. Hence $s_{\xi} = s_{a^*} s_{a^*} s_{\xi} = s_{a^*} P s_{a^*} s_{\xi} \in C^*(\Lambda)PC^*(\Lambda)$. It follows that the generators of $C^*(\Lambda)$ belong to the ideal generated by
$P$, so $P$ is full. For the final statement, fix $v \in V_0$. The first statement of the Lemma gives $vX = v\Lambda \leq Ne_1$. Hence $s_v = \sum_{\alpha \in X} s_\alpha s_\alpha^*$ by (CK4). It follows that

$$P = \sum_{v \in V_0} s_v = \sum_{v \in V_0} \sum_{\alpha \in X} s_\alpha s_\alpha^* = \sum_{\alpha \in X} s_\alpha s_\alpha^*,$$

because $X = \bigcup_{v \in V_0} vX$. □

**Lemma 4.5.** Let $(\Lambda, d)$ be a rank-2 Bratteli diagram of depth $N$ such that the sources in $f^*_1\Lambda$ all lie on a single isolated cycle in $f^*_2\Lambda$. Let $P$ be the projection $P = \sum_{v \in V_0}s_v$, and let $X := V_0(f^*_1\Lambda)V_N$. For each edge $e_* \in V_N\Lambda^2$, there is an isomorphism $\pi : PC^*(\Lambda)P \to M_X(C(\mathbb{T}))$ such that

$$\pi(s_\alpha s_\mu s_\beta^*)(z) = z^{(\mu,e_*)}\Theta(\alpha, \beta) \text{ for all } \alpha, \beta \in X \text{ and } \mu \in s(\alpha)(f^*_2\Lambda)s(\beta)$$

where $\langle \mu, e_* \rangle$ is the number of occurrences of $e_*$ in $\mu$ as in Notation 3.4.

**Proof.** Let $Y$ be the set $(f^*_1\Lambda)V_N$ of paths appearing in Proposition 3.3, which then gives an isomorphism $\pi : C^*(\Lambda) \to M_Y(C(\mathbb{T}))$. By Lemma 4.4, $P$ is full. Restricting $\pi$ to $PC^*(\Lambda)P$ gives an injection, also called $\pi$ which satisfies (1.3) and has range $M_X(C(\mathbb{T})) \subset M_Y(C(\mathbb{T}))$. □

**Corollary 4.6.** Let $(\Lambda, d)$, $P$ and $X$ be as in Lemma 4.5.

1. There is an isomorphism $\phi_0 : K_0(PC^*(\Lambda)P) \to \mathbb{Z}$ such that $\phi_0([s_\alpha s_\beta^*]) = 1$ for every $\alpha \in X$; and
2. For $\alpha \in X$, let $\lambda(\alpha)$ be the isolated cycle in $f^*_2\Lambda$ whose range and source are equal to $s(\alpha)$. Then there is an isomorphism $\phi_1 : K_1(PC^*(\Lambda)P) \to \mathbb{Z}$ such that

$$\phi_1\left([s_\alpha s_\lambda(\alpha)s_\alpha^* + \sum_{\beta \in X \setminus \{\alpha\}} s_\beta s_\beta^*]\right) = 1$$

for every $\alpha \in X$.

**Proof.** The rank-1 projections $\Theta(\alpha, \alpha) \in M_X(C(\mathbb{T}))$ all represent the same class in $K_0(M_X(C(\mathbb{T})))$, and this class is the identity of $K_0$. Likewise the unitaries $z \mapsto z\Theta(\alpha, \alpha) + \sum_{\beta \neq \alpha} \Theta(\beta, \beta)$ all have the same class in $K_1(M_X(C(\mathbb{T})))$ and this class is the identity of $K_1$. The result therefore follows from Lemma 4.5 □

**Lemma 4.7.** Let $(\Lambda, d)$ be a rank-2 Bratteli diagram of depth $N$ and write $V_N = \bigcup_{j=1}^{c_N} V_{N,j}$ as before. Let $Y = (f^*_1\Lambda)V_N$ and $X = V_0(f^*_1\Lambda)V_N$ as before, and let $X_j := V_0(f^*_1\Lambda)V_{N,j}$ for $1 \leq j \leq c_N$. Let $P = \sum_{V \in V_0}s_v$.

1. There is an isomorphism $\phi_0 : K_0(PC^*(\Lambda)P) \to \mathbb{Z}^{c_N}$ such that $\phi_0([s_\alpha s_\lambda(\alpha)s_\alpha^*]) = e_j$ for every $\alpha \in X_j$.
2. For each $\alpha \in X$, let $\lambda(\alpha)$ be the isolated cycle in $s(\alpha)(f^*_2\Lambda)s(\alpha)$. There is an isomorphism $\phi_1 : K_1(PC^*(\Lambda)P) \to \mathbb{Z}^{c_N}$ such that

$$\phi_1\left([s_\alpha s_\lambda(\alpha)s_\alpha^* + \sum_{\beta \in X \setminus \{\alpha\}} s_\beta s_\beta^* + \sum_{\beta \in X_k \setminus \{\alpha\}} s_\beta s_\beta^*]\right) = e_j$$

for every $\alpha \in X_j$.

**Proof.** By Lemma 4.4, we have $P = \sum_{\alpha \in X} s_\alpha s_\alpha^* = \sum_{j=1}^{c_N} \sum_{\alpha \in X_j} s_\alpha s_\alpha^*$. Let $P_j := \sum_{\alpha \in X_j} s_\alpha s_\alpha^*$ for each $j$. The $P_j$ are mutually orthogonal, and hence $PC^*(\Lambda)P = \bigoplus_{j=1}^{c_N} P_j C^*(\Lambda)P_j$. We saw in Proposition 3.3 that if $\Lambda_j := \{\rho \in \Lambda : s(\rho)\Lambda V_{N,j} \neq \emptyset\}$,
then \( \Lambda_j \) is a rank-2 Bratteli diagram in which the sources in \( f_1^* \Lambda_j \) lie on a single isolated cycle in \( f_2^* \Lambda_j \), and there is an injection \( \iota_j \) of \( C^*(\Lambda_j) = C^*\{\{t_{\lambda}\}\} \) into \( C^*(\Lambda) \) which carries \( t_{\alpha}t_{\mu}t_{\beta}^* \) to \( s_\alpha s_\mu s_\beta^* \) for \( \alpha, \beta \in Y_j := YV_{N,j} \). For each \( j \), let \( P(\Lambda_j) \in C^*(\Lambda_j) \) be the projection obtained by applying Lemma 4.4. Then each injection \( \iota_j \) restricts to an isomorphism of \( P(\Lambda(\Lambda_j)C^*(\Lambda_j))P(\Lambda_j) \) onto \( P_jC^*(\Lambda)P_j \).

Let \( \phi^j_1 : K_1(P_jC^*(\Lambda)P_j) \rightarrow \mathbb{Z} \) be the isomorphisms obtained from Corollary 4.6 so for \( \alpha \in X_j \), we have \( \phi^j_1([s_\alpha s_\alpha]) = 1 \) and

\[
\phi^j_1\left(\left[ s_\alpha s_{\lambda(\alpha)} s_\alpha^* + \sum_{\beta \in X_j \setminus \{\alpha\}} s_\beta s_\beta^* + \sum_{\beta \in X_k, k \neq j} s_\beta s_\beta^* \right]\right) = 1.
\]

These injections combine to give the desired isomorphisms \( \phi_* := \bigoplus_{k=1}^{c_N} \phi^k_* \) from

\[
K_*(PC^*(\Lambda)P) = \bigoplus_{k=1}^{c_N} K_*(P_kC^*(\Lambda)P_k) \quad \text{onto} \quad \bigoplus_{k=1}^{c_N} \mathbb{Z} = \mathbb{Z}^{c_N}.
\]

To see that this satisfies (4.21) for each \( j \), fix \( 1 \leq j \leq c_N \). For each \( k \), the class \( \left[ \sum_{\beta \in X_j} s_\beta s_\beta^* \right]_1 \) is the identity element of the direct summand \( K_1(P_kC^*(\Lambda)P_k) \). Hence the class of the unitary

\[
s_\alpha s_{\lambda(\alpha)} s_\alpha^* + \sum_{\beta \in X_j \setminus \{\alpha\}} s_\beta s_\beta^* + \sum_{\beta \in X_k, k \neq j} s_\beta s_\beta^*
\]

represents the generator of the \( j \)th summand of \( \bigoplus_{k=1}^{c_N} K_1(P_kC^*(\Lambda)P_k) \) and the zero element in the other summands.

We now consider a rank-2 Bratteli diagram \( \Lambda \) of infinite depth. For each \( N \in \mathbb{N} \), we consider the sub 2-graph \( \Lambda_N := \left( \bigcup_{n=0}^{N} V_n \right)\Lambda\left( \bigcup_{n=0}^{N} V_n \right) \) consisting of paths connecting vertices in the first \( N \) levels of \( \Lambda^0 \) only.

**Lemma 4.8.** Let \( \Lambda \) be a rank-2 Bratteli diagram of infinite depth. For each \( N \in \mathbb{N} \), the subalgebra \( C^*(\{s_\rho : \rho \in \Lambda_N\}) \) of \( C^*(\Lambda) \) is canonically isomorphic to \( C^*(\Lambda_N) \). If we use these isomorphisms to identify the \( C^*(\Lambda_N) \) with the subalgebras of \( C^*(\Lambda) \), then

\[
(4.5) \quad C^*(\Lambda) = \bigcup_{N=1}^{\infty} C^*(\Lambda_N).
\]

Moreover, \( P = \sum_{v \in V_0} s_v \) is a full projection in \( C^*(\Lambda) \) and in each \( C^*(\Lambda_N) \), and

\[
(4.6) \quad PC^*(\Lambda)P = \bigcup_{N=1}^{\infty} PC^*(\Lambda_N)P.
\]

**Proof.** For each \( N \in \mathbb{N} \), the 2-graph \( \Lambda_N \) is locally convex in the sense of [21], and the elements \( \{s_\rho : \rho \in \Lambda_N\} \) form a Cuntz-Krieger \( \Lambda_N \)-family in \( C^*(\Lambda) \). Thus an application of the gauge-invariant uniqueness theorem [24] Theorem 4.1] gives the required isomorphism of \( C^*(\Lambda_N) \) onto \( C^*(\{s_\rho : \rho \in \Lambda_N\}) \). Since each generator of \( C^*(\Lambda) \) lies in some \( C^*(\Lambda_N) \), we have (4.5).

The projection \( P \) is full in each \( C^*(\Lambda_N) \) by Lemma 4.4. Hence the ideal generated by \( P \) in \( C^*(\Lambda) \) contains the dense subalgebra \( \bigcup_{N=1}^{\infty} C^*(\Lambda_N) \) and it follows that \( P \) is full in \( C^*(\Lambda) \). Since compression by \( P \) is continuous, (4.6) follows from (4.5). \( \square \)

**Proof of Theorem 4.3 (2).** Lemma 4.8 implies that the projection \( P = \sum_{v \in V_0} s_v \) is full. Hence the inclusion \( PC^*(\Lambda)P \subset C^*(\Lambda) \) induces isomorphisms on K-theory. The direct limit decomposition of \( PC^*(\Lambda)P \) in (4.6) and the continuity of \( K \)-theory imply that

\[
K_*(C^*(\Lambda)) = K_*(PC^*(\Lambda)P)) = \lim K_*(PC^*(\Lambda_N)P).
\]

---

**David Pask, Iain Raeburn, Mikael Rørdam, and Aidan Sims**
It therefore suffices to show that the inclusions $i_N : C^*(Λ_N) \hookrightarrow C^*(Λ_{N+1})$ and the isomorphisms $\phi^N$ of $K_*(PC^*(Λ_N)P)$ with $\mathbb{Z}^cN$ provided by Lemma 4.7 fit into commutative diagrams

\[
\begin{array}{ccc}
K_0(PC^*(Λ_N)P) & \xrightarrow{\phi^N_0} & \mathbb{Z}^cN \\
\downarrow (i_N)_* & & \downarrow \text{An} \\
K_0(PC^*(Λ_{N+1})P) & \xrightarrow{\phi^N_{N+1}} & \mathbb{Z}^{cN+1}
\end{array} \quad \quad
\begin{array}{ccc}
K_1(PC^*(Λ_N)P) & \xrightarrow{\phi^N_1} & \mathbb{Z}^cN \\
\downarrow (i_N)_* & & \downarrow \text{Bn} \\
K_1(PC^*(Λ_{N+1})P) & \xrightarrow{\phi^N_{N+1}} & \mathbb{Z}^{cN+1}
\end{array}
\]

(4.7)

Fix $N \in \mathbb{N}$ and $j \leq c_N$.

As in Lemma 4.7 we write $X^N := V_0(f^*Λ)V_N$ and decompose $X^N = \bigsqcup_{j=1}^{c_N} X_j^N$. The inclusion $i_N$ of $C^*(Λ_N)$ in $C^*(Λ_{N+1})$ carries $s_\alpha s^*_\alpha$ into $\sum e \in s(\alpha)\Lambda^e 1 s_{\alpha e} s^*_{\alpha e}$. For each $i \leq c_N$, exactly $A_N(i,j)$ of the paths $\alpha e$ lie in $X_i^{N+1}$, and hence the class of $s_\alpha s^*_\alpha$ in $K_0(PC^*(Λ_{N+1})P)$ is given by

$$[s_\alpha s^*_\alpha] = \left[ \sum_{e \in s(\alpha) \Lambda^e} s_{\alpha e} s^*_{\alpha e} \right] = \sum_{e \in s(\alpha) \Lambda^e} \left[ s_{\alpha e} s^*_{\alpha e} \right] = \sum_{i=1}^{c_N+1} A_N(i,j)e_i.$$ This establishes the commuting diagram on the left of (4.7).

Now for the diagram on the right of (4.7). For $1 \leq j \leq c_N$, let $e_j$ denote the generator of the $j^{th}$ copy of $\mathbb{Z}$ in $K_1(PC^*(Λ_N)P)$. We set $M := \text{lcm}\{A_N(i,j) : 1 \leq i \leq c_{N+1}, A_N(i,j) \neq 0\}$, and compute the image of $M e_j$ in $K_1(PC^*(Λ_{N+1})P)$. Let $\alpha \in X_j^N$. By Lemma 4.7

\[
M e_j = \left[ s_\alpha s^*_\lambda(\alpha)^M s^*_\alpha + \sum_{\beta \in X^N \setminus \{\alpha\}} s_{\beta f} s^*_{\beta f} \right].
\]

(4.8)

The effect of multiplying by $M$ is that if $e \in s(\alpha)\Lambda^e_i V_{N+1,i}$, then the path $\lambda(\alpha)^Me$ factors as $\sigma_i(e)\lambda(\alpha e)^M_i$ where the integer $M_i$ is related to $M$ by

\[
M|V_{N,i}| = M_i|V_{N+1,i}|,
\]

(4.9)

and where $\sigma_i$ is a permutation of $s(\alpha)\Lambda^e_i V_{N+1,i}$ which preserves the source map. The inclusion $i_N$ of $C^*(Λ_N)$ in $C^*(Λ_{N+1})$ carries the right-hand side of (4.8) to the class of

\[
S := \sum_{e \in s(\alpha) \Lambda^e} s_\alpha s^*_\lambda(\alpha)^M s_{\alpha e} s^*_{\alpha e} + \sum_{\beta \in X^N \setminus \{\alpha\}} s_{\beta f} s^*_{\beta f}
\]

\[
= \left( \sum_{i=1}^{c_{N+1}} \sum_{e \in s(\alpha) \Lambda^e_i V_{N+1,i}} s_\alpha s^*_\lambda(\alpha)^M_i s^*_{\alpha e} \right) + \left( \sum_{\beta \in X^N \setminus \{\alpha\}} s_{\beta f} s^*_{\beta f} \right).
\]

To express $S$ in terms of our generators for $K_1(PC^*(Λ_{N+1})P)$, let

\[
U := \sum_{1 \leq i \leq c_N+1} s_{\alpha e} s^*_{\alpha \sigma(e)} + \sum_{\beta \in X^N \setminus \{\alpha\}} s_{\beta f} s^*_{\beta f}.
\]
Then $U$ is unitary because the $\sigma_i$ are permutations. Moreover,

$$US = \left( \sum_{i=1}^{c_{N+1}} \sum_{e \in s(\alpha)\Lambda^i V_{N+1,i}} s_{ae}s_{\lambda(\alpha)e}m_i s_{ae}^* + \sum_{\beta \in X^N \setminus \{\alpha\}} \sum_{f \in s(\beta)\Lambda^i} s_{\beta f} s_{\beta f}^* \right).$$

For any choice of distinguished edges in the isolated cycles at level $N+1$, the associated isomorphism of $PC^*(\Lambda_{N+1})P$ onto $\bigoplus_{i=1}^{c_{N+1}} M_{X_{N+1}}(C(\mathbb{T}))$ obtained from Propositions 3.5 and 3.11 takes $U$ to a constant function, and hence $[U]$ is the identity element of $K_1(PC^*(\Lambda)P)$. Thus $(i_n)_*(Me_j) = [S] = [U] + [S] = [US]$. Moreover,

$$[US] = \left( \sum_{i=1}^{c_{N+1}} \sum_{e \in s(\alpha)\Lambda^i V_{N+1,i}} s_{ae}s_{\lambda(\alpha)e}m_i s_{ae}^* + \sum_{\beta \in X^N \setminus \{\alpha\}} \sum_{f \in s(\beta)\Lambda^i} s_{\beta f} s_{\beta f}^* \right)$$

$$= \prod_{i=1}^{c_{N+1}} \prod_{e \in s(\alpha)\Lambda^i V_{N+1,i}} \left( s_{ae}s_{\lambda(\alpha)e}m_i s_{ae}^* + \sum_{\beta \in X^N \setminus \{ae\}} s_{\beta f} s_{\beta f}^* \right)$$

$$= \sum_{i=1}^{c_{N+1}} \sum_{e \in s(\alpha)\Lambda^i} M_ie_i \quad \text{by (4.4)}$$

$$= \sum_{i=1}^{c_{N+1}} |s(\alpha)\Lambda^i V_{N+1,i}| M_ie_i.$$

Hence

$$(4.10) \quad (i_N)_*(e_j) = \frac{1}{M} \sum_{i=1}^{c_{N+1}} |s(\alpha)\Lambda^i V_{N+1,i}| M_ie_i = \sum_{i=1}^{c_{N+1}} A_N(i,j) M_i \frac{M_i}{M} e_i.$$

Recall from (4.9) that for each $i$, the quantities $M$ and $M_i$ satisfy $M|V_{N,j}| = M_i|V_{N+1,i}|$. By Lemma 4.2(3), we also have $A_N(i,j)|V_{N,j}| = B_N(i,j)|V_{N+1,i}|$, so

$$M_i = \frac{B_N(i,j)}{A_N(i,j)}.$$

Substituting this into (4.10) gives

$$(i_N)_*(e_j) = \sum_{i=1}^{c_{N+1}} B_N(i,j)e_i,$$

and this establishes the commuting diagram on the right of (4.7).

To conclude the proof of Theorem 4.3, it remains to prove assertion (4). The idea is as follows. We construct a 1-graph $B$ such that $C^*(B)$ is AF and $K_0(C^*(B))$ is canonically isomorphic to $K_0(C^*(\Lambda))$. We use the classifications of ideals in the $C^*$-algebras of graphs which satisfy condition (K) [20, Theorem 6.6] and the classification of gauge-invariant ideals in the $C^*$-algebras of $k$-graphs [24, Theorem 5.2] to establish a lattice isomorphism between the ideals of $C^*(B)$ and the gauge-invariant ideals of $C^*(\Lambda)$. Finally, we use [30, Theorem 1.5.3] to obtain an isomorphism from the lattice of ideals of $C^*(B)$ to the lattice of order-ideals of $K_0(C^*(B))$.

The next result amounts to a restatement of results of Bratteli [3] and Elliott [2] in the language of 1-graph algebras. We give the result and the proof here for two reasons: firstly, the language and notation of 1-graph algebras is more convenient to our later arguments than the traditional notation of Bratteli diagrams; and secondly, we want
to establish explicit formulas linking the \( K_0 \)-group and ideal structure of \( C^* (\Lambda) \) for a rank-2 Bratteli diagram \( \Lambda \) to the \( K_0 \)-group and ideal structure of an associated AF graph algebra.

**Proposition 4.9.** Let \( \Lambda \) be a rank-2 Bratteli diagram of infinite depth, and let \( c_n, A_n, B_n, T_n \) be the data associated to \( \Lambda \). Let \( B \) be the 1-graph with vertices \( B^0 = \bigcup_{n=0}^{\infty} W_n \) where \( W_n = \{ w_{n,1}, \ldots, w_{n,v_n} \} \) and with \( A_n(i,j) \) edges from \( w_{n+1,i} \) to \( w_{n,j} \) for all \( n, i, j \). Let \( \{ t_\beta : \beta \in B \} \) be the universal generating Cuntz-Krieger \( B \)-family in \( C^* (B) \), and let \( Q := \sum_{w \in W_0} t_w \). Then

1. \( Q \) is a full projection in \( C^* (B) \);
2. for \( n \in \mathbb{N} \), the set \( F_n = \text{span} \{ s_\alpha s_\beta^* : \alpha, \beta \in W_0 B W_0 \} \) is a subalgebra of \( C^* (B) Q \) and is canonically isomorphic to \( \bigoplus_{j=1}^{\infty} M_{W_0 B W_0} (\mathbb{C}) \);
3. \( F_n \subset F_{n+1} \) for all \( n \), and \( C^* (B) Q \) is equal to \( \bigcup_{n=1}^{\infty} F_n \) and hence is a unital AF algebra;
4. there is an isomorphism \( \phi : K_0 (PC^* (\Lambda) P) \to K_0 (C^* (B) Q) \) which satisfies \( \phi ([s_\eta s_{\eta'}^*]) = [t_\beta t_\beta^*] \) for all \( \eta \in V_0 (f_1^* \Lambda) V_{n,j} \) and \( \beta \in W_0 B W_{n,j} \); and
5. there is a lattice isomorphism between the ideals of \( C^* (B) Q \) and the gauge-invariant ideals of \( PC^* (\Lambda) P \) which takes \( J < C^* (B) Q \) to the ideal generated by \( \{ s_\eta s_{\eta'}^* : \eta \in V_0 (f_1^* \Lambda) V_{n,j}, s_\beta s_{\beta'}^* \in J \, \forall \, \beta \in W_0 B W_{n,j} \} \) in \( PC^* (\Lambda) P \).

**Proof.** An argument more or less identical to the proof of [23 Proposition 2.12] establishes claims (1), (2) and (3).

(4) For \( \beta \in W_0 B W_{n,j} \), \( t_\beta t_\beta^* \) is a minimal projection in the \( j \)-th summand of \( F_n \) and hence its class in \( K_0 (F_n) \) is the \( j \)-th generator \( e_j \) of \( \mathbb{Z}_{c_n} \). The inclusion map \( \iota : F_n \to F_{n+1} \) takes a minimal projection \( t_\beta t_\beta^* \in F_n \) to \( \sum_{e \in s(\beta) B^1} t_\beta t_\beta^* \in F_{n+1} \). Hence \( t_\beta t_\beta^* \) embeds in the \( j \)-th summand of \( F_{n+1} \) as a projection of rank \( |s(\beta) B^1 w_{n+1,i}| = A_n(i, j) \). It follows that

\[
K_0 (C^* (B) Q) = \lim_{\rightarrow} (K_0 (F_n), K_0 (\iota)) = \lim_{\rightarrow} (\mathbb{Z}_{c_n}, A_n)
\]

and this is equal to \( K_0 (PC^* (\Lambda) P) \) by Theorem 4.3.2.

Equation (4.11) shows that for \( \beta \in W_0 B W_{n,j} \), the class of \( t_\beta t_\beta^* \) in \( K_0 (C^* (B) Q) \) is \( A_{\infty,n} (e_j) \). But this is precisely the class of \( s_\eta s_{\eta'}^* \) in \( K_0 (PC^* (\Lambda) P) \) for any \( \eta \in V_0 (f_1^* \Lambda) V_{n,j} \) by Lemma 4.4.2 and the left-hand commuting diagram of equation (4.1).

(5) Since \( B \) has no cycles, it satisfies condition (K) of [20]. Hence [20 Theorem 6.6] implies that the lattice of ideals of \( C^* (B) \) is isomorphic to the lattice of saturated hereditary subsets of \( B^0 \) via \( I \mapsto H_I := \{ v : s_v \in I \} \). We have \( I = \text{span} \{ t_\alpha t_\beta^* : s(\alpha) = s(\beta) \in H_I \} \). Since (1) shows that \( Q \) is full, the map \( I \mapsto Q I Q \) is a lattice-isomorphism between ideals of \( C^* (B) \) and ideals of \( C^* (B) Q \). Hence if \( J \) is an ideal in \( C^* (B) Q \), we can sensibly define \( H_J := H_I \) where \( J = Q I Q \), and we have \( J = \text{span} \{ t_\alpha t_\beta^* : \alpha, \beta \in W_0 B H_J \} \).

A similar analysis, using [24 Theorem 5.2] instead of [20 Theorem 6.6] shows that the lattice of gauge-invariant ideals of \( PC^* (\Lambda) P \) is isomorphic to the lattice of saturated hereditary subsets of \( \Lambda^0 \) via \( J \mapsto J ) \) for \( \tau \in V_0 \). For \( \tau \in \Lambda \) we can decompose \( \tau = \eta \mu \) where \( \eta \in f_1 \Lambda \) and \( \mu \in f_2 \Lambda \), and we have \( s_\tau s_{\tau'}^* = s_\eta s_{\eta'}^* \). If \( H \) is hereditary, then \( s(\tau) \in H \) and only if \( s(\eta) \in H \) because \( \Lambda \) satisfies condition (3.1).
Hence \( J \mapsto \{ v : s_\eta s_\eta^* \in J \text{ for } \eta \in \mathcal{V}_0(f_*^* \Lambda \nu) \} \) is a lattice-isomorphism between gauge-invariant ideals of \( PC^*(\Lambda)P \) and saturated hereditary subsets of \( \Lambda^0 \).

Now if \( H \subset \Lambda^0 \) is hereditary, then for \( n \in \mathbb{N} \) and \( 1 \leq j \leq c_n \), either \( V_{n,j} \subset H \) or \( V_{n,j} \cap H = \emptyset \). It is easy to check using this that there is a bijection between the saturated hereditary subsets of \( B^0 \) and those of \( \Lambda^0 \) characterised by \( H \subset B^0 \mapsto \bigcup\{ V_{n,j} : w_{n,j} \in H \} \), and this completes the proof. \( \square \)

**Proof of Theorem 4.3(4).** Let \( B \) be the 1-graph of Proposition 4.9. Proposition 4.9(3) shows that \( QC^*(B)Q \) is AF, so it is stably finite and has real-rank zero \([30\text{ p 23}]. By [30] Theorem 1.5.3, the map \( J \mapsto K_0(J) \) is therefore an isomorphism from the ideal lattice of \( QC^*(B)Q \) to the order-ideal lattice of \( K_0(QC^*(B)Q) \).

The image of an ideal \( J \) in \( K_0(QC^*(B)Q) \) is equal to \( \lim_{\rightarrow} (K_0(J \cap F_n), A_n|_{K_0(J \cap F_n)}) \). Since the ideals of \( F_n \) are precisely its direct summands, \( J \cap F_n \) is a direct sum of some subset of the direct summands of \( F_n \), and so \( K_0(J \cap F_n) = \langle t_{\beta}^* t_{\beta} : t_{\beta}^* \in J \cap F_n \rangle \). Hence \( K_0(J) = \langle t_{\beta}^* t_{\beta} : t_{\beta}^* \in J \rangle \subset K_0(QC^*(B)Q) \). By Proposition 4.9(4), it follows that the image \( \phi^{-1}(K_0(J)) \) of \( K_0(J) \) in \( K_0(PC^*(\Lambda)P) \) is equal to

\[
\{ [s_\eta s_{\eta}^*] : \eta \in V_0(f_1^* \Lambda V_{n,j}^*), s_\eta s_{\eta}^* \in J \text{ for } \beta \in W_0 B w_{n,j} \}.
\]

Proposition 4.9(5) now establishes that there is an isomorphism \( \theta \) from the lattice of gauge-invariant ideals of \( PC^*(\Lambda)P \) to the lattice of order-ideals of \( K_0(PC^*(\Lambda)P) \) which takes \( J \) to \( \{ [s_\eta s_{\eta}^*] : s_\eta s_{\eta}^* \in J \} \).

Since \( P \) is full, compression by \( P \) induces an isomorphism \( \phi_P \) of \( K_0(C^*(\Lambda)) \) onto \( K_0(PC^*(\Lambda)P) \). For \( \eta \in f_1^* \Lambda \), we have \( s_\eta s_{\eta}^* \sim s_{s(\eta)} \), so \( [s_{s(\eta)}] = [s_{\eta} s_{\eta}^*] \in K_0(C^*(\Lambda)). \)
Since each \( s_\eta s_{\eta}^* \leq P \) it follows that \( \phi([s_{s(\eta)}]) = [s_{\eta} s_{\eta}^*] \in K_0(PC^*(\Lambda)P) \). Hence

\[
\theta(J) = \phi_P([s_\eta] : v = s(\eta) \text{ for some } \eta \text{ with } s_\eta s_{\eta}^* \in J)
\]

for each ideal \( J \in PC^*(\Lambda)P \). For an ideal \( I \) of \( C^*(\Lambda) \), \( s_\eta s_{\eta}^* \in PIP \) if and only if \( s_\eta \in I \). Since \( P \) is full and gauge-invariant, \( I \mapsto PIP \) is an isomorphism between the lattice of gauge-invariant ideals of \( C^*(\Lambda) \) and that of \( PC^*(\Lambda)P \). Thus \( I \mapsto \phi_P^{-1}(\theta(PIP)) \) is the desired lattice-isomorphism. \( \square \)

**Order units and dimension range.** Given a \( C^* \)-algebra \( A \), we write \( D_0(A) \) for the dimension range

\[
D_0(A) = \{ [p]_0 : p \in A \text{ is a projection} \} \subset K_0(A).
\]

Elliott’s classification theorem implies that if \( A \) is a simple \( AT \) algebra with real-rank zero, then \( A \) is determined up to isomorphism by the data \( (K_0(A), K_1(A), [1_A]_0) \) if \( A \) is unital, and by the data \( (K_0(A), K_1(A), D_0(A)) \) if \( A \) is non-unital (see [30] Theorem 3.2.6 and the subsequent discussion). In Section 4.1 we identify conditions on a rank-2 Bratteli diagram \( \Lambda \) which ensure that \( C^*(\Lambda) \) (and hence \( PC^*(\Lambda)P \)) is simple and has real-rank zero, so it is worth identifying the class \([P] \in K_0(PC^*(\Lambda)P) \) and the dimension range \( D_0(C^*(\Lambda)) \subset K_0(C^*(\Lambda)) \).

**Lemma 4.10.** Let \( \Lambda \) be a rank-2 Bratteli diagram of infinite depth.

1. There is an order-isomorphism of \( K_0(PC^*(\Lambda)P) \) onto \( \varinjlim (\mathbb{Z}^{c_n}, A_n) \) which takes \([P]\) to the image of \( ([V_{0,1}], \ldots, V_{0,c_0}] \in \mathbb{Z}^{c_0} \), and an isomorphism of \( K_1(PC^*(\Lambda)P) \) onto \( \varinjlim (\mathbb{Z}^{c_n}, B_n) \).
(2) For $n \in \mathbb{N}$ and $1 \leq j \leq c_n$ let $Y_{n,j} := (f_j^* \Lambda) V_{n,j}$, and let $D_n$ denote the subset $\{m \in \mathbb{Z}^{c_n} : 0 \leq m_j \leq |Y_{n,j}| \text{ for each } 1 \leq j \leq c_n\}$. The isomorphism of $K_0(C^*(\Lambda))$ onto $\lim_{n \to \infty} (\mathbb{Z}^{c_n}, A_n)$ described in Theorem 4.3(2) takes $D_0(C^*(\Lambda))$ to the subset $\bigcup_{n=0}^{\infty} A_{n,\infty}(D_n)$.

Proof. The first statement follows from Lemmas 4.7 and 4.8. The second statement follows from a similar argument using Corollary 3.12 to see that the isomorphism of $C^*(\Lambda)$ onto $\bigoplus_{j=1}^{c_n} M_{Y_{n,j}}(C(\mathbb{T}))$ takes the class of the identity in $K_0(\Lambda)$ to $(|Y_{n,1}|, \ldots, |Y_{n,c_n}|) \in \mathbb{Z}^{c_n}$ for each $n$.

Remark 4.11. For any choice of vertices $v_j \in V_{n,j}$, it is easy to check that the projection $p = \sum_{j=1}^{c_n} s_{v_j}$ is full in $\Lambda$, and we can use Theorem 4.3 and Lemmas 4.7 and 4.8 to see that there is an order-isomorphism of $K_0(p\Lambda)\{\mathbb{Z}^{c_n}, A_n\}$ which takes $[p]$ to the usual order-unit $A_{\infty,0}(1, \ldots, 1)$.

5. LARGE-PERMIUTAION FACTORISATIONS, SIMPLICITY, AND REAL RANK ZERO

In this section we characterise the rank-2 Bratteli diagrams $\Lambda$ whose $C^*$-algebras are simple, and describe a condition on $\Lambda$ which ensures that $C^*(\Lambda)$ has real rank zero. Elliott’s classification theorem for $\Lambda$-algebras (see Theorem 3.2.6 and the discussion that follows it in [30]) then implies that $C^*(\Lambda)$ is determined up to isomorphism by its $K$-theory.

In a rank-2 Bratteli diagram the factorisation property induces a permutation $\mathcal{F}$ of the set $f^*_1 \Lambda$ of blue paths: for $\alpha \in f^*_1 \Lambda$, let $f$ be the unique red edge with $s(f) = r(\alpha)$, and define $\mathcal{F}(\alpha)$ to be the unique blue path such that $f\alpha = \mathcal{F}(\alpha)f'$ for some red edge $f'$. (In the notation of §3, $\mathcal{F}(\alpha) = \mathcal{F}_1(f, \alpha)$.) For $\alpha \in f^*_1 \Lambda$, the order $o(\alpha)$ of $\alpha$ is the smallest $k > 0$ such that $\mathcal{F}^k(\alpha) = \alpha$. If $r(\alpha) \in V_{n,j}$ and $\mu$ is the unique red path with $s(\mu) = r(\alpha)$ and $|\mu| = o(\alpha)$, then $\mu\alpha$ has the form $\alpha\mu'$, and $\mu = \lambda(r(\alpha))^n$ for $m = o(\alpha)/|V_{n,j}|$.

Recall from [18, Definition 4.7] that a $k$-graph $\Lambda$ is cofinal if for every vertex $v$ and every infinite path $x$ there exists $n \in \mathbb{N}^2$ such that $v\Lambda x(n)$ is nonempty.

Theorem 5.1. Let $\Lambda$ be a rank-2 Bratteli diagram. Then $C^*(\Lambda)$ is simple if and only if $\Lambda$ is cofinal and $\{o(e) : e \in \Lambda^e\}$ is unbounded.

To prove the theorem, we first need to establish some properties of the order function $o$.

Lemma 5.2. Let $\Lambda$ be a rank-2 Bratteli diagram.

1. Suppose that $\alpha = \mu \sigma\nu$ and $\alpha = \beta \gamma\eta$ are two factorisations of $\alpha \in \Lambda$ in which $d(\mu)$ and $d(\beta)$ have the same 1st coordinates and $g, h \in \Lambda^e_1$. Then $o(g) = o(h)$.

2. For every blue path $\beta$ of length $n$, $o(\beta) = \text{lcm}(o(\beta_1), \ldots, o(\beta_n))$.

Proof. For (1), write $d(\mu) = (n, k)$ and $d(\beta) = (n, l)$, and without loss of generality suppose $l \geq k$. Then $\mu_0((n, k)) = \alpha_0((n, k)) = \delta$, say, and the factorisation property implies that $\beta = \delta \beta'$. Since $d(\beta') = (l - k)e_2$, $\beta'$ is the unique red path of length $l - k$ from $r(\delta)$ to $s(\delta) = r(g)$. Thus $g$ is the image $\mathcal{F}^{l-k}(h)$ of $h$ under the $(l - k)^{th}$ iteration of the permutation $\mathcal{F}$, and hence has the same order as $h$. (This is a general property of permutations of sets.)
For (2), notice that the uniqueness of factorisations implies that
\[ \mathcal{F}^k(\beta) = \mathcal{F}^k(\beta_1)\mathcal{F}^k(\beta_2) \cdots \mathcal{F}^k(\beta_n) \]
is equal to \( \beta \) if and only if \( \mathcal{F}^k(\beta_i) = \beta_i \) for all \( i \).

**Corollary 5.3.** Let \( \Lambda \) be a rank-2 Bratteli diagram, and suppose that \( \mu\alpha = \alpha'\mu' \) where \( \mu, \mu' \) are red and \( \alpha, \alpha' \) are blue. Then \( o(\alpha) = o(\alpha') \).

We aim to prove simplicity of \( C^*(\Lambda) \) by verifying that \( \Lambda \) satisfies the aperiodicity Condition (A) of [13], so we begin by recalling some definitions from [13]. We denote by \( \Omega_k \) the \( k \)-graph with vertices \( \Omega^0_\kappa := \mathbb{N}^k \), paths \( \Omega^m_\kappa = \{(n, n + m) : n \in \mathbb{N}^k \} \) for \( m \in \mathbb{N}^k \), \( r((n, n + m)) = n \) and \( s((n, n + m)) = n + m \). The infinite paths in a \( k \)-graph \( \Lambda \) with no sources are the degree preserving functors \( x : \Omega_k \to \Lambda \). The collection of all infinite paths of \( \Lambda \) is denoted \( \Lambda^\infty \), and the range of \( x \) is the vertex \( x(0) \). For \( p \in \mathbb{N}^k \) and \( x \in \Lambda^\infty \), \( \sigma^p(x) \in \Lambda^\infty \) is defined by \( \sigma^p(x)(n) := (x(n + p) \) in Definitions 2.1. A path \( x \in \Lambda^\infty \) is aperiodic if \( \sigma^p(x) = \sigma^q(x) \) implies \( p = q \).

The next lemma will help us recognise aperiodic paths.

**Lemma 5.4.** Suppose that \( x \) is an infinite path in a rank-2 Bratteli diagram \( \Lambda \) such that \( o(x(0, ne_1)) \to \infty \) as \( n \to \infty \). Then \( x \) is aperiodic.

**Proof.** Suppose that \( p, q \in \mathbb{N}^2 \) satisfy \( \sigma^p(x) = \sigma^q(x) \). We must show that \( p = q \). If \( n \) is the integer such that \( r(x) \in V_n \), then \( r(\sigma^p(x)) \in V_{n+p} \) and \( r(\sigma^q(x)) \in V_{n+q} \). Thus \( \sigma^p(x) = \sigma^q(x) \) implies that \( p_1 = q_1 \). Without loss of generality, we may suppose \( q_2 \geq q_2 \). Now the infinite path \( y := \sigma^{p_2-q_2}(x) = \sigma^{(q_2-p_2)}(x) \) satisfies \( \sigma^l(y) = y \) where \( l := q_2 - p_2 \), so \( y = y(0, le_2)y \). Since \( o(x(0, p_1e_1)) \) is finite, Corollary 5.3 implies that the path \( y \) also satisfies \( o(y(0, ne_1)) \to \infty \) as \( n \to \infty \). But for every \( n \) we have
\[ y(0, ne_1) = (y(0, le_2)y)(0, ne_1) = \mathcal{F}^l(y(0, ne_1)), \]
and hence we must have \( l = 0 \), \( p_2 = q_2 \) and \( p = q \).

**Proof of sufficiency in Theorem 5.7.** Suppose that \( \Lambda \) is cofinal and \( \{o(e) : e \in \Lambda^{e_1} \} \) is unbounded. To show that \( C^*(\Lambda) \) is simple, it suffices by [13] Proposition 4.8 to show that for each \( w \in \Lambda^0 \) there is an aperiodic path \( x \) with \( r(x) = w \).

We first claim that for every \( v \in \Lambda^0 \) there exists \( N \) such that \( v\Lambda V_{N,i} \) is nonempty for every \( i \leq c_N \). To prove this, we suppose to the contrary that there exists \( v \in \Lambda^0 \), say \( v \in V_n \), and a sequence \( \{i_m : m > n \} \) such that \( v\Lambda V_{m,i_m} = \emptyset \) for all \( m \). By assumption the sinks in \( \Lambda \) belong to \( V_0 \), so for each \( m > n \) there exists a path \( \xi_m \in V_n\Lambda V_{m,i_m} \). Let \( p_0 := \{\xi_m : m > n \} \). Since \( \Lambda \) is row-finite, there exists \( g_1 \in V_n\Lambda^{e_1} \) such that \( p_1 := \{\eta \in p_0 : \eta(0, e_1) = g_1 \} \) is infinite. For the same reason, there then exists \( g_2 \in s(g_1)\Lambda^{e_1} \) such that \( p_2 := \{\eta \in p_1 : \eta(e_1, 2e_1) = g_2 \} \) is infinite. Continuing in this way, we obtain a sequence \( g_i \) of blue edges such that for each \( i \) there are infinitely many \( m \) with \( \xi_m(0, i e_1) = g_1 \ldots g_i \). By choice of the \( \xi_m \), then we have \( v\Lambda s(g_i) = \emptyset \) for all \( i \). For each \( i \), let \( x_i := g_1\Lambda(s(g_1))g_2\Lambda(s(g_2)) \ldots g_i\Lambda(s(g_i)) \). By [13] Remark 2.2, there is a unique infinite path \( x \in \Lambda^\infty \) such that \( x(0, d(x_i)) = x_i \) for all \( i \). By construction, we have \( v\Lambda x(n) = \emptyset \) for all \( n \in \mathbb{N}^2 \). This contradicts the cofinality of \( \Lambda \), and we have justified the claim.

We now fix \( w \in \Lambda^0 \), and construct an aperiodic path with range \( v \). By the claim there exists \( N \in \mathbb{N} \) such that \( v\Lambda V_{N,j} \neq \emptyset \) for all \( j \leq c_N \). Since the sinks in \( \Lambda^0 \) belong
to $V_0$, we then have $w\Delta V_{M,i} \neq \emptyset$ for all $M \geq N$ and $i \leq c_M$. Since $\sup\{o(e) : e \in \Lambda^{e_1}\} = \infty$, and since $\bigcup_{n=0}^{N-1} V_n\Lambda^{e_1}$ is finite, there exists $M \geq N$ and $g \in V_M\Lambda^{e_1}$ such that $o(g) \geq 2$. By choice of $g$ there exists a path $\alpha_2 \in v\Lambda g$, and we may assume that $d(\alpha_2) \geq (1, 1)$. Repeating this procedure at the vertex $v = s(\alpha_2)$ gives a path $\alpha_3 \in s(\alpha_2)\Lambda$ such that $o(\alpha_3)(d(\alpha_3) - e_1, d(\alpha_3)) \geq 3$ and $d(\alpha_3) \geq (1, 1)$. By continuing this way we can inductively construct a sequence of paths $\alpha_i$ with $s(\alpha_i) = r(\alpha_{i+1})$,
\[d(\alpha_i) \geq (1, 1)\text{ and } o(\alpha_i)(d(\alpha_i) - e_1, d(\alpha_i)) \geq i.\]By \cite{18} Remark 2.2, there is a unique infinite path $x$ such that $x(0, d(\alpha_2) + \cdots + d(\alpha_i)) = \alpha_2 \cdots \alpha_i$ for all $i$. Part (1) of Lemma \ref{lem:5.2} implies that $d(x(0, ne_1)) \geq o(\alpha_i)(d(\alpha_i) - e_1, d(\alpha_i)) \geq i$ for sufficiently large $n$, and hence $d(x(0, ne_1)) \to \infty$ as $n \to \infty$. Thus it follows from Lemma \ref{lem:5.4} that $x$ is aperiodic, and since $r(x) = r(\alpha_2) = w$, this completes the proof. 
\[\Box\]

For the other direction in Theorem \ref{thm:5.1} we show that if $\{o(e)\}$ is bounded then the graph is periodic, and apply the following general result.

**Proposition 5.5.** Let $\Lambda$ be a row-finite $k$-graph. Suppose that there is a vertex $v \in \Lambda^0$ and an element $p \in \mathbb{N}^k$ such that every $x \in v\Lambda^\infty$ satisfies $x = \sigma^p(x)$. Then $C^*(\Lambda)$ is not simple.

**Proof.** Let $\{S_\lambda : \lambda \in \Lambda\}$ be the Cuntz-Krieger family on $\ell^2(\Lambda^\infty)$ given by $S_\lambda e_x = \delta_{\lambda(x)} r(x) e_{\lambda x}$ \cite[Proposition 2.11]{18}. Then $S_\lambda^* e_x = \delta_{\lambda(x)(0, d(\lambda))} e_{\sigma^p(\lambda)(x)}$ for all $\lambda \in \Lambda$ and $x \in \Lambda^\infty$. Let $\pi_S$ be the corresponding representation of $C^*(\Lambda)$.

Fix $\mu \in v\Lambda^p$. By assumption on $v\Lambda^\infty$,
\[S_\mu^* e_x = \delta_{\mu,x(0,p)} e_{\sigma^p(x)} = \delta_{\mu,x(0,p)} e_x = S_\mu S_\mu^* e_x \]
for all $x \in \Lambda^\infty$. Hence $S_\mu^* = S_\mu S_\mu^*$. Let $\gamma$ be the gauge action on $C^*(\Lambda)$. Fix $z \in \mathbb{T}^k$ such that $\overline{\varphi^p} = -1$. Then $\gamma_z(s_\mu^*) = -s_\mu^*$ and $\gamma_z(s_\mu s_\mu^*) = s_\mu s_\mu^*$, so $s_\mu s_\mu^* - s_\mu^* \neq 0$. However $\pi_S(s_\mu s_\mu^* - s_\mu^*) = S_\mu S_\mu^* - S_\mu^* = 0$, so the kernel of $\pi_S$ is a nontrivial ideal in $C^*(\Lambda)$. \[\Box\]

**Proof of necessity in Theorem 5.1** Suppose that $C^*(\Lambda)$ is simple. Let $B$ be the 1-graph associated to $\Lambda$ as in Proposition 4.9. By Proposition 4.9(5), $QC^*(B)Q$ is simple, so Proposition 4.9(1) shows that $C^*(B)$ is simple. It now follows from \cite[Proposition 5.1]{1} that $B$ is cofinal, and from the definition of $B$ that $\Lambda$ is also cofinal.

We now argue by contradiction that $\{o(e) : e \in \Lambda^{e_1}\}$ is unbounded. Suppose to the contrary that $o(e) \leq l$ for all $e \in \Lambda^{e_1}$. Then $o(e)$ divides $l!$ for all $e \in \Lambda^{e_1}$. Let $p = l!e_2$. We claim that $\sigma^p(x) = x$ for every $x \in \Lambda^\infty$. To compute $\sigma^p(x)$, we first factor $x$ as
\[(5.1) x = \mu g_1 \lambda(s(g_1)) g_2 \lambda(s(g_2)) \ldots \]
where $d(\mu) = p$ and $d(g_1) = e_1$. Since $o(g_1)$ divides $l!$ and $\mu$ is the unique path of length $l!$ starting at $r(g_1)$, $\mu g_1$ has the form $g_1 \mu_1$ where $d(\mu_1) = d(\mu) = p$. Since the cycle $\lambda(s(g_1))$ is isolated, we have $\mu_1 \lambda(s(g_1)) g_2 = \lambda(s(g_1)) \mu_1 g_2$. Now $\mu_1$ is the unique red path of length $l!$ starting at $r(g_2)$. Since $o(g_2)$ divides $l!$, $\lambda(s(g_1)) \mu_1 g_2$ has the form $\lambda(s(g_1)) g_2 \mu_2$ where $d(\mu_2) = d(\mu_1) = p$. Continuing this way shows that we can also factor $x$ as
\[x = g_1 \lambda(s(g_1)) g_2 \lambda(s(g_2)) \ldots,\]
and then \cite{2} implies that $\sigma^p(x) = x$, establishing the claim. Proposition 5.5 now implies that $C^*(\Lambda)$ is not simple, which is a contradiction. \[\Box\]
We now turn our attention to the problem of deciding when \( C^*(\Lambda) \) has real-rank zero.

**Definition 5.6.** We say that a rank-2 Bratteli diagram \( \Lambda \) has *large-permutation factorisations* if for each \( v \in \Lambda^0 \) and each integer \( l > 0 \) there exists \( N \in \mathbb{N} \) such that

\[
o(\alpha) > l \text{ for all } \alpha \in v\Lambda^{N\mathbb{N}}.
\]

Since rank-2 Bratteli diagrams are row-finite, a rank-2 Bratteli diagram with large-permutation factorisations must have infinite depth, and Lemma 5.4 implies that every infinite path in \( \Lambda \) is aperiodic.

There are several ways to ensure that a rank-2 Bratteli diagram has large-permutation factorisations. For example, this is automatically the case if the red cycles get larger as \( n \) grows, or more precisely if \( \min_j |V_{n,j}| \to \infty \) as \( n \to \infty \). Alternatively, we can keep \( |V_{n,j}| \) small but add lots of blue edges entering each \( V_{n,j} \) and define the factorisation property to ensure that \( \min \{ o(e) : r(e) \in V_n \} \to \infty \) as \( n \to \infty \).

**Theorem 5.7.** Let \( \Lambda \) be a rank-2 Bratteli diagram with large-permutation factorisations.

1. Every ideal of \( C^*(\Lambda) \) is gauge-invariant, and the lattice of ideals of \( C^*(\Lambda) \) is isomorphic to the lattice of order-ideals of \( K_0(C^*(\Lambda)) \) via the map described in Theorem 4.3(4).
2. If \( \Lambda \) is cofinal, then \( C^*(\Lambda) \) is simple and \( C^*(\Lambda) \) has real-rank zero.

To prove Theorem 5.7(2), we show that the projections in \( C^*(\Lambda) \) separate the tracial states with a view to applying [2, Theorem 1.3].

Recall that for \( \alpha \in \Lambda \), \( \lambda(\alpha) \) denotes the isolated cycle with range and source \( s(\alpha) \). For the next result, we adopt the convention that for a negative integer \( m \), \( s_{\lambda(\alpha)^m} := s_{\lambda(\alpha)^{-m}} \).

**Lemma 5.8.** Let \( \Lambda \) be a rank-2 Bratteli diagram and let \( \tau \) be a trace on \( C^*(\Lambda) \). Let \( \alpha, \beta \in f_1^*\Lambda \) and \( \mu \in f_2^*\Lambda \). Suppose that \( \tau(s_\alpha s_\mu s_\beta^*) \neq 0 \) or that \( \tau(s_\alpha s_\beta s_\mu^*) \neq 0 \). Then \( \alpha = \beta \) and \( \mu = \lambda(\alpha)^m \) for some \( m \in \mathbb{Z} \).

**Proof.** We argue the case where \( \tau(s_\alpha s_\mu s_\beta^*) \neq 0 \); the other case is similar. Since \( \tau \) is a trace, we have \( \tau(s_\beta^*s_\alpha s_\mu) = \tau(s_\alpha s_\mu s_\beta^*) \neq 0 \). Since \( \mu \in f_2^*\Lambda \), both \( s(\alpha) \) and \( s(\beta) \) belong to the same level of the rank-2 Bratteli diagram \( \Lambda \); say \( s(\alpha), s(\beta) \in V_n \). Furthermore, since \( s_\beta^*s_\alpha s_\mu \neq 0 \), the ranges of \( \alpha \) and \( \beta \) must coincide, and in particular belong to the same \( V_m \). Since \( \Lambda \) is a rank-2 Bratteli diagram it follows that \( d(\alpha) = d(\beta) = (n-m)e_1 \). This forces \( \alpha = \beta \). But now \( r(\mu) = s(\beta) = s(\alpha) = s(\mu) \), and it follows that \( \mu = \lambda(\alpha)^m \) for some \( m \in \mathbb{N} \).

**Lemma 5.9.** Let \( \Lambda \) be a rank-2 Bratteli diagram. Suppose that \( \Lambda \) has large-permutation factorisations, and let \( \tau \) be a trace on \( C^*(\Lambda) \). If \( \alpha \in f_1^*\Lambda \) and \( \tau(s_\alpha s_{\lambda(\alpha)^m} s_\alpha^*) \neq 0 \), then \( m = 0 \).

**Proof.** We show that \( m > 0 \) implies that \( \tau(s_\alpha s_{\lambda(\alpha)^m} s_\alpha^*) = 0 \); a similar argument shows that \( m < 0 \) is also impossible, so that \( m \) must be 0.
So suppose that \( m > 0 \). Taking \( v = s(\alpha) \) and \( l = m|\lambda(\alpha)| \) in Definition \ref{def:rank2} we obtain an integer \( n \) such that for all \( \beta \in v\Lambda_{ne} \), \( \mathcal{F}^{m|\lambda(v)|}(\beta) \neq \beta \). But now

\[
\tau(s_\alpha s_{\lambda(v)}^m s_\alpha^*) = \tau\left( \sum_{\beta \in v\Lambda_{ne}} s_\alpha s_{\lambda(v)}^m s_\beta s_\beta^* s_\alpha^* \right) \quad \text{by (CK4)}
\]

\[
= \sum_{\beta \in v\Lambda_{ne}} \tau(s_\alpha \mathcal{F}^{m|\lambda(v)|}(\beta) s_\beta s_\beta^* s_\alpha^*)
\]

where for each \( \beta, \mu(\beta) \) is the unique element of \( s(\beta)\Lambda \) of degree \( d(\lambda(v)^m) \). By choice of \( n, \alpha \mathcal{F}^{m|\lambda(v)|}(\beta) \neq \alpha\beta \) for each term in the sum, and it follows from Lemma \ref{lem:trace} that \( \tau(s_\alpha s_{\lambda(v)}^m s_\alpha^*) = 0 \).

\[\square\]

**Corollary 5.10.** Let \( \Lambda \) be a rank-2 Bratteli diagram with large-permutation factorisations. Then the projections in \( C^*(\Lambda) \) separate traces on \( C^*(\Lambda) \).

**Proof.** Let \( \tau_1 \) and \( \tau_2 \) be traces on \( C^*(\Lambda) \) which agree on all the projections in \( C^*(\Lambda) \). Then \( \tau_1(s_\alpha s_\alpha^*) = \tau_2(s_\alpha s_\alpha^*) \) for all \( \alpha \in f_1\Lambda \). By Lemmas \ref{lem:trace} and \ref{lem:trace2} it follows that \( \tau_1 \) and \( \tau_2 \) agree on \( \text{span} \{s_\alpha s_\mu s_\beta, s_\alpha s_\beta s_\mu : \alpha, \beta \in f_1\Lambda, \mu \in f_2\Lambda \} \), which by Lemma \ref{lem:trace4} and the first assertion of Lemma \ref{lem:trace5} is all of \( C^*(\Lambda) \). Thus \( \tau_1 = \tau_2 \). \[\square\]

**Proof of Theorem \[5.7\]** If \( H \) is a saturated hereditary subset of \( \Lambda^0 \), then \( \Gamma_H := \Lambda \setminus \Lambda H = \{ \eta \in \Lambda : s(\eta) \notin H \} \) is a \( k \)-graph by \cite[Theorem 5.2(b)]. Theorem 5.3 of \cite{2} implies that if \( \Gamma_H \) satisfies \cite[Condition (B)]{2} for every saturated hereditary \( H \subset \Lambda^0 \), then every ideal of \( C^*(\Lambda) \) is gauge-invariant. Remark (4.4) of \cite{2} shows that if \( \Gamma_H \) has no sources and satisfies the aperiodicity condition \cite[Condition (A)]{13}, then \( \Gamma_H \) satisfies \cite[Condition (B)]{2}. It therefore suffices to show that if \( H \subset \Lambda^0 \) is saturated and hereditary, then \( \Gamma_H \) has no sources and satisfies the aperiodicity condition.

Fix a saturated hereditary subset \( H \) of \( \Lambda^0 \). If \( v \in \Gamma_H \), then \( v\Lambda^{e_1} \) is nonempty. If \( v\Lambda^{e_1} \subset \Lambda H \), then \( v \in H \) because \( H \) is saturated, contradicting \( v \in \Gamma_H \). Thus there exists \( e \in v\Lambda^{e_1} \setminus \Lambda H = v\Gamma_H \), and \( \Gamma_H \) has no sources. Each infinite path of \( \Gamma_H \) is also an infinite path of \( \Lambda \), and hence is aperiodic by Lemma \ref{lem:aperiodic}. Thus \( \Gamma_H \) satisfies the aperiodicity condition of \cite{13}.

The rest of (1) now follows from Theorem \ref{thm:aperiodic}.

For (2), we first deduce from Lemma \ref{lem:aperiodic2} that \( \{s(e) : e \in \Lambda^{e_1} \} \) has to be unbounded, and hence Theorem \ref{thm:aperiodic} implies that \( C^*(\Lambda) \) is simple. Corollary \ref{cor:aperiodic} implies that the projections in \( C^*(\Lambda) \) separate the tracial states. Theorem \ref{thm:aperiodic2} guarantees that \( C^*(\Lambda) \) is an \( \mathcal{AT} \) algebra. By \cite[Theorem 1.3]{2}, a simple \( \mathcal{AT} \) algebra \( A \) has real-rank zero if and only if the projections of \( A \) separate the tracial states, and this proves the result. \[\square\]

**6. Achievability of Classifiable Algebras**

In this section we characterise the \( K \)-group pairs which can arise as those of \( PC^*(\Lambda)P \) when \( \Lambda \) is a rank-2 Bratteli diagram with large-permutation factorisations. We have already shown that the data associated to a rank-2 Bratteli diagram \( \Lambda \) consists of integers \( c_n \), matrices \( A_n, B_n \in M_{c_{n+1},c_n}(\mathbb{Z}_+) \) with no zero rows or columns, and diagonal matrices \( T_n \in M_{c_n}(\mathbb{Z}_+) \) with positive diagonal entries such that \( K_0(C^*(\Lambda)) = \varinjlim(\mathbb{Z}^{c_n}, A_n) \), \( K_1(C^*(\Lambda)) = \varinjlim(\mathbb{Z}^{c_n}, B_n) \), and \( A_n T_n = T_{n+1} B_n \) for all \( n \). Here we establish a converse and characterise the \( K \)-groups that can arise when \( PC^*(\Lambda)P \) is simple with real-rank zero.
Definition 6.1. We say that an integer matrix $M$ is proper if all entries of $M$ are nonnegative, and each row and each column of $M$ contains at least one nonzero entry (cf [1 §A4]). Note that a diagonal matrix is proper if and only if all diagonal entries are nonzero.

The data associated to a rank-2 Bratteli diagram always consists of proper matrices.

**Theorem 6.2.**

1. Let $\Lambda$ be a rank-2 Bratteli diagram of infinite depth and suppose that $C^*(\Lambda)$ is simple. Then $K_0(C^*(\Lambda))$ is a simple dimension group which is not isomorphic to $\mathbb{Z}$.

2. Let $\{c_n : n \in \mathbb{N}\}$ be positive integers. For each $n$, let $A_n, B_n \in M_{c_{n+1},c_n}(\mathbb{Z}_+)$ be proper matrices, and let $T_{c_n} \in M_n(\mathbb{Z}_+)$ be a proper diagonal matrix. Suppose additionally that $A_nT_n = T_{n+1}B_n$ for all $n$. Then there exists a rank-2 Bratteli diagram $\Lambda$ such that $K_0(C^*(\Lambda)) \cong \varprojlim (\mathbb{Z}^{c_n}, A_n)$ and $K_1(C^*(\Lambda)) \cong \varprojlim (\mathbb{Z}^{c_n}, B_n)$. If $\varprojlim (\mathbb{Z}^{c_n}, A_n)$ is simple dimension group which is not isomorphic to $\mathbb{Z}$, then $\Lambda$ can be chosen so that $C^*(\Lambda)$ is simple with real-rank zero.

**Remark 6.3.** In Theorem 6.2(2), we do not claim that there is a rank-2 Bratteli diagram $\Lambda$ with data $c_n, A_n, B_n, T_n$. We can always build a rank-2 Bratteli diagram $\Lambda$ with the specified data (see Proposition 6.4), and if $\varprojlim (\mathbb{Z}^{c_n}, A_n)$ is a simple dimension group, then $\Lambda$ will be cofinal. However, to ensure that $C^*(\Lambda)$ is simple and has real-rank zero, we construct a rank-2 Bratteli diagram with large-permutation inclusions, and to do this, we have to choose a subsequence of $\mathbb{N}$ and adjust the data $c_n, A_n, B_n, T_n$ accordingly.

**Proof of Theorem 6.2(1).** We will show that if $K_0(PC^*(\Lambda)P)$ is isomorphic to $\mathbb{Z}$ or is not simple as a dimension group, then $C^*(\Lambda)$ is not simple. Let $B$ be the 1-graph of Proposition 4.9. Then parts (3) and (4) of Proposition 4.7 imply that $QC^*(B)Q$ is a unital AF algebra with $K_0(QC^*(B)Q) = \varprojlim (\mathbb{Z}^{c_n}, A_n)$ isomorphic as a dimension group to $K_0(PC^*(\Lambda)P)$.

First suppose that $K_0(PC^*(\Lambda)P)$ is isomorphic to $\mathbb{Z}$, and hence $QC^*(B)Q \cong M_\mathbb{C}(1)$ where $n = [1,\mathbb{A}]$ is the class of the unit $\mathbb{A}$ of Proposition 7.3.4. Since $QC^*(B)Q$ is finite-dimensional, the approximating subalgebras $F_n$ of Proposition 4.9(2) must equal $QC^*(B)Q$ for large $n$. Thus $F_n$ eventually has just one direct summand, so $c_n = |W_n| = 1$ for large $n$ by Proposition 4.9(2). Moreover, since $F_n = F_{n+1}$ for large $n$, we must have $|W_0BW_n| = |W_0BW_{n+1}|$ for large $n$ by Proposition 4.9(2), so $A_n(1,1) = |W_nB^iW_{n+1}| = 1$ for large $n$, say for $n \geq M$.

Now suppose that $K_0(PC^*(\Lambda)P)$ is not simple as a dimension group. Then the AF algebra $QC^*(B)Q$ is not simple either [30 Corollary 1.5.4], and Proposition 4.9(5) implies that $C^*(\Lambda)$ is not simple. □
For the second claim of the theorem, we need to know how to build a rank-2 Bratteli diagram from the data $c_n, A_n, B_n$ and $T_n$. Recall from Definition 5.6 that for $e \in \Lambda^e$, the order $o(e)$ of $e$ is the length of the shortest nontrivial path $\mu \in f_2^* \Lambda$ such that $(\mu e)(0, e_1) = e$.

**Proposition 6.4.** Let $c_n, A_n, B_n$ and $T_n$ be as in Theorem 6.2(2). There is a rank-2 Bratteli diagram $\Lambda$ with this data which has the following property: for each blue edge $e \in \Lambda$, say $r(e) \in V_{n,j}$ and $s(e) \in V_{n+1,i}$, we have $o(e) = A_n(i,j)|V_{n,j}|$.

**Proof.** Since the data of (4.2) is all contained in the 1-skeleton of the rank-2 Bratteli diagram, [18] Section 6] shows that we need only construct a 1-skeleton with the right number of edges, and an allowable collection of commuting squares so that the order of each blue edge in $V_{n,j}\Lambda^e V_{n+1,i}$ is $A_n(i,j)|V_{n,j}|$. By (4.1), this is equivalent to showing that the order of each blue edge in $V_{n,j}\Lambda^e V_{n+1,i}$ is maximal.

For each $n$, the matrix $T_n$ defines a collection of $c_n$ isolated cycles $\lambda_{n,j}$ ($1 \leq j \leq c_n$) where $\lambda_{n,j}$ has $T_n(j,j)$ vertices. The collection of all paths in these cycles is $f_2\Lambda$, and the vertices on each $\lambda_{n,j}$ are the elements of $V_{n,j}$.

We want to show that for each $j \leq c_n$ and $i \leq c_{n+1}$, we can:

1. add blue edges from vertices in $\lambda_{n+1,i}$ to vertices in $\lambda_{n,j}$ so that the number of blue edges to each vertex on $\lambda_{n,j}$ from $\lambda_{n+1,i}$ is $a := A_n(i,j)$ and the number of blue edges from each vertex on $\lambda_{n+1,i}$ is $b := B_n(i,j)$; and

2. specify an allowed collection of commuting squares so that the resulting permutation of the blue edges in $V_{n,j}\Lambda^e V_{n+1,i}$ is maximal.

Let $v := T_n(j,j)$ be the number of vertices on $\lambda_{n,j}$, and let $w := T_{n+1}(i,i)$ be the number of vertices on $\lambda_{n+1,i}$. The commutativity of (4.2) says that $av = wb$.

We first demonstrate that it suffices to show how to add the desired blue edges when $a$ and $b$ have no common divisors; that is, when $(a,b) = 1$. To see this, suppose that $a = da'$ and $b = db'$, and that we can add the desired edges to obtain the data $A_n(i,j) = a'$ and $B_n(i,j) = b'$. Then we take the resulting diagram, and add $d - 1$ blue edges $e(1), \ldots, e(d)$ parallel to each blue edge $e$, so that we now have $A_n(i,j) = a$ and $B_n(i,j) = b$, and define the factorisation property by lifting the old factorisation cycle $(e, F(e), F^2(e), \ldots, F^{d-1}(e) = e)$ to

$$(e(1), F(e)(1), \ldots, F^{d-1}(e)(1), e(2), F(e)(2), \ldots, F^{d-1}(e)(d), e(1)).$$

Next we demonstrate that it suffices to show how to add the desired blue edges when $(v,w) = 1$. To see this, suppose that $v = dv'$ and $w = dw'$, and that we can add the desired edges in the diagram corresponding to $T_n(i,i) = v'$ and $T_{n+1}(j,j) = w'$. Then we may take the resulting diagram, add $d - 1$ vertices between pairs of consecutive vertices on $\lambda_{n,j}$ and on $\lambda_{n+1,i}$ and augment each commuting square between vertices on $\lambda_{n,j}$ and $\lambda_{n+1,i}$ to a sequence of $d - 1$ commuting squares as shown in Figure 2 for $d = 3$.

The factorisation property is uniquely determined in each of these augmented paths, and we obtain a diagram with the desired data $T_n(j,j) = v$ and $T_{n+1}(i,i) = w$. Notice that we have multiplied both the order of the factorisation permutation and the number of edges in the picture by the same number $d$.

Finally, we demonstrate how to add the desired blue edges when $(a,b) = 1$ and $(v,w) = 1$. To do this, note that the conditions $(a,b) = 1$ and $(v,w) = 1$ together force
\[ a = w \text{ and } v = b. \] Now adding the complete bipartite graph from the vertices on \( \lambda_{n,j} \) to the vertices on \( \lambda_{n+1,i} \) gives a 1-skeleton with the desired data and a unique factorisation property. We have \( r(F_1(\mu, e)) = r(e) \) if and only if \( d(\mu) = kve_2 \) for some \( k \in \mathbb{N} \) and \( s(F_1(\mu, e)) = s(e) \) if and only if \( d(\mu) = lwe_2 \) for some \( l \). Since \( (v, w) = 1 \), it follows that \( F_1(\mu, e) \neq e \) for \( 0 < d(\mu) < vw = va. \)

Proof of Theorem 6.2(2). The first claim follows immediately from Proposition 6.4 and Theorem 4.3(2). Now suppose that \( \lim_n(\mathbb{Z}^n, A_n) \) is simple and is not isomorphic to \( \mathbb{Z} \). For \( n \geq m \) let \( A_{n,m} := A_{n-1}A_{n-2} \ldots A_m \). We begin by showing that there is a subsequence \((\ell(n)) \) of \( \mathbb{N} \) for which all entries of \( A_{\ell(n+1), \ell(n)} \) are at least \( n \).

Since the matrices \( A_n \) are proper, the second paragraph of the proof of [7, Lemma A4.3] shows that we can find a subsequence \( k(n) \) of \( \mathbb{N} \) such that all the entries in the matrices \( A_{k(n+1), k(n)} \) are positive and nonzero. Since \( G \neq \mathbb{Z} \), [7, Lemma A4.4] implies that for every \( m \in \mathbb{Z}^{c_{k(n)}} \),

\[
\min\{ (A_{k(l),k(n)m})_i : 1 \leq i \leq c_{k(l)} \} \to \infty \quad \text{as} \quad l \to \infty.
\]

It follows that for each \( N \in \mathbb{N} \) there exists \( l \geq n \) such that every entry of \( A_{k(l),k(n)} \) is greater than \( N \). Thus there is a subsequence \( \ell(n) \) of \( k(n) \) such that every entry of \( A_{\ell(n+1),\ell(n)} \) is at least \( n \).

Now \( \{\ell(n)\} \) is cofinal in \( \mathbb{N} \) and each \( A_{\ell(n+1),\ell(n)} \) is proper by choice. So if we let \( c'_n := c_{\ell(n)}, A'_n := A_{\ell(n+1),\ell(n)}, B'_n := B_{\ell(n+1),\ell(n)} \) and \( T'_n := T_{\ell(n)} \) for all \( n \), we obtain a commuting diagram of the form (4.2) in which every entry of \( A'_n \) is at least \( n \).

Let \( \Lambda \) be the rank-2 Bratteli diagram obtained by applying Proposition 6.4 to the data \( c'_n, A'_n, B'_n, T'_n \). For a blue edge \( e \) with range in \( V_n \), the order of \( e \) is bounded below by the smallest entry of \( A'_n \), hence is at least \( n \). Thus condition (5.2) holds for \( N = 1 \). Hence \( \Lambda \) has large-permutation factorisations.

Now \( PC^*(\Lambda)P \) has the desired \( K \)-theory by Theorem 4.3(2), and it is simple with real-rank zero because it is a full corner in \( C^*(\Lambda) \), which is such an algebra by Theorem 5.7(2) (see [21, Theorem 3.1.8]).

Example 6.5 (The irrational rotation algebras). Fix an irrational number \( \theta \in (0,1) \). The irrational rotation algebra \( A_\theta \) is the universal \( C^* \)-algebra generated by unitaries \( U, V \) satisfying \( UV = e^{2\pi i \theta} VU \). Elliott and Evans have proved that that \( A_\theta \) is a simple unital \( AT \) algebra with real-rank zero [11], and work of Rieffel and Pimsner-Voiculescu combines to show that \( K_0(A_\theta) \) is order-isomorphic to \( \mathbb{Z} + \theta \mathbb{Z} \), and \( K_1(A_\theta) \) is isomorphic to \( \mathbb{Z}^2 \) (see [27, 22]).
Let \([a_1, a_2, a_3, \ldots]\) be the unique simple continued fraction expansion for \(\theta\) [15, Theorem 169], and define
\[
A_n := \begin{pmatrix} a_n & 1 \\ 1 & 0 \end{pmatrix}.
\]

Theorem 3.2 of [8] says that \(\mathbb{Z} + \theta \mathbb{Z}\) is order-isomorphic to \(\lim (\mathbb{Z}^2, A_n)\). Let \(T_n := \text{id}_{c_n}\) and let \(B_n = A_n\). Since \(\mathbb{Z} + \theta \mathbb{Z}\) is group-isomorphic to \(\mathbb{Z}^2\), we obtain a commuting diagram of the form (1.2) with \(\lim (\mathbb{Z}^{c_n}, A_n) = \mathbb{Z} + \theta \mathbb{Z}\) and \(\lim (\mathbb{Z}^{c_n}, B_n) = \mathbb{Z}^2\).

Since \(\mathbb{Z} + \theta \mathbb{Z}\) is a simple dimension group, it follows from Theorem 6.2(2) that there is a rank-2 Bratteli diagram \(\Lambda_\theta\) such that \(C^*(\Lambda_\theta)\) is a simple AT algebra with real-rank zero with \(K_0(C^*(\Lambda_\theta))\) order-isomorphic to \(\mathbb{Z} + \theta \mathbb{Z}\), and with \(K_1(C^*(\Lambda_\theta))\) isomorphic to \(\mathbb{Z}^2\). Corollary 4.10 implies that \(PC^*(\Lambda)P\) has the same \(K\)-theory with the usual order-unit for \(K_0\). Now Elliott’s classification theorem for AT algebras (as in [30, Theorem 3.2.6]) implies that \(PC^*(\Lambda_\theta)P\) is isomorphic to \(A_\theta\).

To draw such a rank-2 Bratteli diagram \(\Lambda_\theta\), take \(A_n\) as above. If \(\ell(n) := n(n+1)/2\) is the sequence of triangular numbers, then every entry of \(A_{\ell(n+1), \ell(n)}\) is greater than or equal to \(n\). Let \(\phi_n := A_{\ell(n+1), \ell(n)}\) for all \(n\). Then the skeleton of \(\Lambda_\theta\) is illustrated by Figure 3, where the label \(n\) on a solid edge indicates the presence of \(n\) parallel blue edges. The factorisation rules are specified by \(\lambda(v)e = \sigma(e)\lambda(v)\) for maximal permutations \(\sigma\) of parallel blue edges.

**Example 6.6.** More generally, let \(G\) be a simple dimension group other than \(\mathbb{Z}\). Write \(G = \lim (\mathbb{Z}^{c_n}, A_n)\), let \(T_n := \text{id}_{c_n}\) and let \(B_n = A_n\). As above, we obtain a rank-2 Bratteli diagram \(\Lambda(G)\) such that \(PC^*(\Lambda(G))P\) is a simple unital \(C^*\)-algebra with real-rank zero, \(K_0(PC^*(\Lambda(G))P)\) is order-isomorphic to \(G\) with the usual order unit and \(K_1(PC^*(\Lambda(G))P)\) is group-isomorphic to \(G\). Elliott’s classification theorem for AT algebras then implies that \(PC^*(\Lambda(G))P\) is the unique AT algebra with these properties.

**Example 6.7** (The Bunce-Deddens algebras). As in [31, Section 7.4], a **supernatural number** is a sequence \(m = (m_k)_{k=1}^{\infty}\) where each \(m_i \in \{0, 1, 2, \ldots, \infty\}\). We think of \(m\) as the formal product \(\prod_{i=1}^{\infty} p_i^{m_i}\) where \(p_i\) is the \(i\)th prime number. We say \(m\) is **infinite** if \(\prod_{i=1}^{\infty} p_i^{m_i} = \infty\), or equivalently if \(\sum_{j=1}^{\infty} m_j = \infty\).

For each supernatural number \(m\), \(Q(m)\) denotes the subgroup of \(\mathbb{Q}\) consisting of the fractions of the form \(x(\prod_{i=1}^{N} \frac{1}{p_j^{m_j}})\) with \(0 \leq q_j \leq m_j\) for all \(j\). Each \(Q(m)\) is a simple dimension group. If \(m\) is finite, then \(Q(m) \cong \mathbb{Z}\), so there is no simple AT algebra with

**Figure 3.** A rank-2 Bratteli diagram for the irrational rotation algebra \(A_\theta\).
real-rank zero and $K_0$-group $Q(m)$. If $m$ is infinite, then $Q(m)_+$ contains no minimal elements, and so $Q(m)$ is not isomorphic to $\mathbb{Z}$. Elliott’s classification theorem says there is a unique simple unital $\mathbb{A}_T$-algebra $A$ with real-rank zero and $(K_0(A), K_1(A)) = (Q(m), \mathbb{Z})$. This $C^*$-algebra is known as the Bunce-Deddens algebra of type $m$; there are several concrete realisations of these algebras, for example as the $C^*$-algebras generated by families of weighted shifts (see [4] or [5, V.3]), or as crossed products by odometer actions (see [5, §VIII.4]). We will demonstrate that for each infinite supernatural number $m$ there is a rank-2 Bratteli diagram $\Lambda(m)$ such that $PC^*(\Lambda(m))P$ is isomorphic to the Bunce-Deddens algebra of type $m$.

Fix an infinite supernatural number $m$. Let $\{p_j\}_{j=1}^\infty$ be any sequence of primes in which each prime $p_j$ occurs with cardinality $m_j$. Then $\varprojlim(\mathbb{Z} \times \mathbb{Z}) \cong Q(m)$ by [31, Lemma 7.4.4]. For $n \in \mathbb{N}$, let $c_n := 1$, let $A_n := [a_n]$, let $B_n := [1]$ and let $T_n := [a_n]$. This data gives a diagram of the form [12] in which $\varprojlim([\mathbb{Z}^{\infty}, A_n] = Q(m)$ and $\varprojlim([\mathbb{Z}^{c_n}, B_n]) = \mathbb{Z}$. It follows from Theorem 6.2(2) that there is a rank-2 Bratteli diagram $\Lambda(m)$ such that $C^*(\Lambda(m))$ is simple and has real-rank zero and $K$-groups $Q(m), \mathbb{Z}$. Corollary 4.10 implies that $PC^*(\Lambda)P$ has the same $K$-theory with the usual order-unit for $K_0$. Elliott’s classification theorem then implies that $PC^*(\Lambda(m))P$ is isomorphic to the Bunce-Deddens algebra of type $m$.

For example, the skeleton of $\Lambda(2^\infty)$ is given in Figure 4; the factorisation rules are uniquely determined by the skeleton.

**Figure 4.** A rank-2 Bratteli diagram for the Bunce-Deddens algebra of type $2^\infty$.

7. **Rank-2 Bratteli diagrams with length-1 cycles**

In this section we restrict attention to rank-2 Bratteli diagrams in which all the isolated cycles have length 1. We show that in this situation, the associated inclusions of circle algebras are *standard permutation mappings*, and that every directed system of
direct sums of circle algebras under standard permutation mappings arises from a rank-2 Bratteli diagram in which all the isolated cycles have length 1. In the next section we use this to investigate simplicity, real-rank and the trace simplex of the associated $C^*$-algebra in greater detail than the results obtained for general rank-2 Bratteli diagrams in the previous sections. To state the main theorem of this section, we first need to set up some notation.

Let $\mathcal{M}(\mathbb{T})$ denote the set of (positive) probability measures on $\mathbb{T}$. Each $\mu \in \mathcal{M}(\mathbb{T})$ induces a functional on $C(\mathbb{T})$, again denoted by $\mu$, given by integration

$$
\mu(f) = \int_{\mathbb{T}} f \, d\mu, \quad f \in C(\mathbb{T}).
$$

Thus $\mathcal{M}(\mathbb{T})$ is a subset of $(C(\mathbb{T}))^*$ whence it inherits the weak-* topology.

A Markov operator on $C(\mathbb{T})$ is a positive linear mapping $E: C(\mathbb{T}) \to C(\mathbb{T})$ that maps the constant function 1 to itself. Each Markov operator $E$ induces an affine mapping $\hat{E}: \mathcal{M}(\mathbb{T}) \to \mathcal{M}(\mathbb{T})$ given by $\hat{E}(\mu)(f) = \mu(E(f))$ which is continuous both wrt. the weak-* and the norm topology on $\mathcal{M}(\mathbb{T})$.

For each $\theta \in \mathbb{R}$ let $\rho_\theta$ be the Markov operator on $C(\mathbb{T})$ given by rotation by angle $\theta$, that is, $\rho_\theta(f)(z) = f(e^{i\theta}z)$. For each $k \in \mathbb{N}$, let $R_k$ be the Markov operator

$$
R_k = \frac{1}{k} \sum_{j=0}^{k-1} \rho_{2\pi j/k}.
$$

Observe that

$$
R_k \circ R_\ell = R_{\text{lcm}(k,\ell)}.
$$

It follows from (7.2) that if $N$ is a natural number, and if $E_1, E_2 \in \text{conv}\{R_k : k \mid N\}$ and $F_1, F_2 \in \text{conv}\{R_k : k \nmid N\}$, then

$$
E_1 E_2 \in \text{conv}\{R_k : k \mid N\}, \quad F_1 E_2, E_1 F_2, F_1 F_2 \in \text{conv}\{R_k : k \nmid N\}.
$$

In agreement with the convention mentioned above, $\hat{\rho}_\theta$ and $\hat{R}_k$ will be the corresponding affine mappings on $\mathcal{M}(\mathbb{T})$.

Given a unital $C^*$-algebra $A$, we write $T(A)$ for the Choquet simplex of tracial states on $A$ endowed with the weak-* topology.

**Definition 7.1.** Let $\sigma$ be a permutation on a finite set $S$. For $s \in S$, $o(s)$ denotes the order $\min\{n > 0 : \sigma^n(s) = s\}$ of $s$ under $\sigma$. We write $\kappa(\sigma)$ for $\max\{o(s) : s \in S\}$. For $\ell \leq |S|$, we write $c_\ell(\sigma)$ for the number of orbits under $\sigma$ of size $\ell$. Note that $\sum_\ell \ell c_\ell(\sigma) = |S|$. For $N \in \mathbb{N}$, we define

$$
\beta_N(\sigma) := \frac{1}{|S|} \sum_{\ell \mid N} \ell c_\ell(\sigma) = \frac{1}{|S|}|\{s \in S : o(s) \text{ divides } N\}|.
$$

The goal of the section is to prove the following theorem. Recall that for a vertex $v$ of a rank-2 Bratteli diagram, the path $\lambda(v)$ is the isolated cycle in $v(f_2^*\Lambda)v$. Recall also that $\mathcal{F}$ denotes the permutation of $f_1^*\Lambda$ of Section 5

**Theorem 7.2.** Let $\Lambda$ be a rank-2 Bratteli diagram of infinite depth in which all red cycles have length 1. For $n \in \mathbb{N}$ and $1 \leq j \leq c_n$, let $v_{n,j}$ be the unique element of $V_{n,j}$.
For $n \in \mathbb{N}$, $1 \leq j \leq c_n$ and $1 \leq i \leq c_{n+1}$, let $F_{n}^{i,j}$ be restriction of $F$ to $v_{n,j} \Lambda^i v_{n+1,i}$. For $N \in \mathbb{N}$, let

$$\alpha_N := \sum_{n \in \mathbb{N}} (1 - \max_{A_n(i,j) \neq 0} \beta_N(F_{n}^{i,j})) \quad \text{and} \quad \overline{\alpha}_N := \sum_{n \in \mathbb{N}} (1 - \min_{A_n(i,j) \neq 0} \beta_N(F_{n}^{i,j})).$$

Let $P = \sum_{v \in V_0} s_v$. Identify $C^*(f_1^* \Lambda)$ with the subalgebra $C^*(\{ \xi : \xi \in f_1^* \Lambda \})$ of $C^*(\Lambda)$. Then $C^*(f_1^* \Lambda)$ is AF and is simple if and only if $\Lambda$ is cofinal. Moreover each trace $\tau$ on $PC^*(\Lambda)P$ restricts to a trace on $PC^*(f_1^* \Lambda)P$. The $AT$ algebra $C^*(\Lambda)$ is simple if and only if $\Lambda$ is cofinal and

$$\sup\{ \kappa(F_{n}^{i,j}) : n \in \mathbb{N}, 1 \leq j \leq c_N, 1 \leq i \leq c_{N+1}, A_n(i,j) \neq 0 \} = \infty.$$

Suppose that $\Lambda$ is cofinal.

1. If $\alpha_N = \infty$ for all $N$, then $C^*(\Lambda)$ is simple, $PC^*(\Lambda)P$ has real-rank zero, and $\tau \mapsto \tau|_{PC^*(f_1^* \Lambda)P}$ determines an isomorphism between the traces on $PC^*(\Lambda)P$ and the traces on $PC^*(f_1^* \Lambda)P$.

2. If $\overline{\alpha}_N < \infty$ for some $N$, then $PC^*(\Lambda)P$ has real-rank one and there is an injective mapping

$$(7.4) \quad T(PC^*(f_1^* \Lambda)P) \times \{ \mu \in M(\mathbb{T}) : \tilde{R}_N(\mu) = \mu \} \to T(PC^*(\Lambda)P) \quad (\tau, \mu) \mapsto \tilde{\tau}_\mu$$

such that $|V_n| = c_n = 1$ for all $n$. Then $PC^*(f_1^* \Lambda)P$ has unique trace and $\overline{\alpha}_N = \alpha_N$ for all $N$. If $|V_N| = c_N < \infty$ for some $N$ then the injection $\tilde{\tau}_N$ is continuous and affine. If $|V_n| = c_n = 1$ for all $n$ and $\overline{\alpha}_1 = \alpha_1 < \infty$ then the injection $\tilde{\tau}_N$ is a homeomorphism of $M(\mathbb{T})$ onto $T(PC^*(\Lambda)P)$.

We will prove this theorem on page 33 after an analysis of the trace simplices of certain $AT$ algebras. To apply the results of this analysis, we need to show that the partial inclusions of circle subalgebras of $C^*(\Lambda)$ in the setting of Theorem 1.2 are of a standard form.

Let $m$ be a natural number, and let $S_m$ denote the group of permutations on $m$ letters. For $\sigma \in S_m$, let $\psi_\sigma : C(\mathbb{T}) \to M_m(C(\mathbb{T}))$ be the $*$-homomorphism which sends the canonical generator $z$ for $C(\mathbb{T})$ into the unitary element $\sum_{j=1}^{m} e_{j,\sigma(j)}$ in $M_m(C(\mathbb{T}))$, where $\{ e_{i,j} \}$ is the set of canonical matrix units for $M_m$. In the special case where $\sigma$ is the $m$-cycle $(1 \ 2 \ 3 \ \cdots \ m)$ the associated $*$-homomorphism $\psi_\sigma$ will also be denoted by $\psi_m$, and it is given by

$$(7.5) \quad \psi_m(z) = \begin{pmatrix} 0 & z & 0 & \cdots & 0 \\ 0 & 0 & z & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & z \\ z & 0 & 0 & \cdots & 0 \end{pmatrix},$$

where again $z$ is the canonical generator of $C(\mathbb{T})$.

If $n, m$ are natural numbers and $\sigma \in S_m$, then we shall also let $\psi_\sigma$ denote the amplified $*$-homomorphism $M_n(C(\mathbb{T})) \to M_{mn}(C(\mathbb{T}))$, or more generally, the not necessarily unital amplified $*$-homomorphism $M_n(C(\mathbb{T})) \to M_k(C(\mathbb{T}))$, where $k$ is any natural number.
greater than or equal to \(mn\), obtained by viewing \(M_{mn}(C(T))\) as a (non-unital) sub-
\(C^*\)-algebra of \(M_k(C(T))\). We refer to a \(^*\)-homomorphism of this form as a standard
permutation mapping.

**Proposition 7.3.** Let \(\Lambda\) be a rank-2 Bratteli diagram of infinite depth in which each
red cycle has length 1. Let \(\pi_n : PC^* (\Lambda_n ) P \to M_{X_n}(C(T)) \otimes C(T)\) be the isomorphisms
obtained from Proposition \(3.5\) and Proposition \(3.11\). For each \(n \in \mathbb{N}, 1 \leq j \leq c_n\) and
\(1 \leq i \leq c_{n+1}\), let \(i_{n}^{ij}\) denote the partial inclusion of the \(j\)th summand of \(PC^* (\Lambda_N ) P\) into
the \(i\)th summand of \(PC^* (\Lambda_{N+1}) P\). Let \(F_n^{ij}\) be as in Theorem \(7.2\). Then \(\pi_{n+1} \circ i_{n}^{ij} \circ \pi_n^{-1}\)
is the standard permutation mapping \(\psi(F_n^{ij})^{-1}\).

**Remark 7.4.** When the red cycles have length 1 we need not distinguish a red edge
e, in each red cycle to obtain the isomorphisms \(\pi_n\). Thus the constant matrix units
in Lemma \(4.5\) are precisely the \(s_a s_b^*\) for \(\alpha, \beta \in f_1^* \Lambda\). If we demand only that all red
cycles have the same length, a result similar to Proposition \(7.3\) holds, but we have to
work much harder to show that \(\pi_{n+1} \circ i_{n}^{ij} \circ \pi_n^{-1}\) is unitarily equivalent to the standard
permutation mapping \(\psi(F_n^{ij})^{-1}\).

Corollary \(7.3\) shows that any direct system of standard permutation mappings can be
realised with the simpler construction where each red cycle has length one, so we omit
the more complicated analysis for longer cycles.

**Proof of Proposition 7.3.** For \(\alpha, \beta \in X_{n,j}\) and \(a, b \in v_{n,j} \Lambda^e v_{n+1,i}\), let
\[
\theta(\alpha, \beta) := s_\alpha s_\beta^* \quad \theta(aa, \beta b) := s_{aa} s_{\beta b}^* \quad \text{and} \quad \theta(a, b) := \sum_{\eta \in X_{n,j}} s_\eta s_{\beta b}^.
\]
Relation (CK4) shows that for \(\alpha, \beta \in X_{n,j}\), the image of \(\theta(\alpha, \beta)\) in \(PC^* (\Lambda_{n+1}) P\) is
equal to
\[
\sum_{a \in v_{n,j} \Lambda^e v_{n+1,i}} s_{aa} s_{\beta a}^ = \sum_{a \in v_{n,j} \Lambda^e v_{n+1,i}} \theta(aa, \beta a).
\]
Using the Cuntz-Krieger relations, we therefore have \(\theta(\alpha, \beta) \theta(a, b) = \theta(aa, \beta b) = \theta(a, b) \theta(\alpha, \beta)\) for all \(\alpha, \beta \in X_{n,j}\) and \(a, b \in v_{n,j} \Lambda^e v_{n+1,i}\).

Since \(PC^* (\Lambda_{n+1}) P\) is generated by the matrix units \(\theta(aa, \beta b), aa, \beta b \in X_{n+1,i}\) and
the unitary \(U_{n+1,i} := \sum_{a \in X_{n+1,i}} s_\alpha s_{\lambda(v_{n+1,i})} s_\alpha^*\), we now have an isomorphism
\[
(7.6) \quad M_{X_{n,j}}(C(T)) \otimes M_{v_{n,j} \Lambda^e v_{n+1,i}}(C(T)) \cong PC^* (\Lambda_{n+1}) P
\]
which takes \(z \mapsto \Theta(\alpha, \beta) \otimes \theta(a, b) \otimes z\) to \(\theta(\alpha, \beta) \theta(a, b) U_{n+1,i}\). Under this identification,
\(\pi_{n+1} \circ i_{n}^{ij} \circ \pi_n^{-1}\) takes \(\Theta(\alpha, \beta)\) to \(\sum_{a \in v_{n,j} \Lambda^e v_{n+1,i}} \Theta(\alpha, \beta) \otimes \theta(a, b) \otimes 1\).

Let \(U_{n,j} := \sum_{a \in X_{n,j}} s_\alpha s_{\lambda(v_{n,j})} s_\alpha^*\). If we identify \(M_{X_{n,j}}(C(T))\) with \(M_{X_{n,j}}(C(T))\)
in the usual way, then \(\pi_n\) takes \(\theta(\alpha, \beta) U\) to \(\Theta(\alpha, \beta) \otimes z\). The partial inclusion of \(PC^* (\Lambda_n) P\)
into \(PC^* (\Lambda_{n+1}) P\) takes \(\theta(\alpha, \beta) U = s_\alpha s_{\lambda(v_{n,j})} s_\alpha^*\) to
\[
\sum_{a \in v_{n,j} \Lambda^e v_{n+1,i}} s_\alpha s_{\lambda(v_{n,j})} s_\alpha s_\beta^ = \sum_{a \in v_{n,j} \Lambda^e v_{n+1,i}} s_\alpha F_n^{ij}(a) s_{\lambda(v_{n+1,i})} s_\alpha^* s_\beta
\]
by (CK4). Hence under the identification \(7.6\),
\[
\pi_{n+1} \circ i_{n}^{ij} \circ \pi_n^{-1}(z) = 1_{X_{n,j}} \otimes \left( \sum_{a \in v_{n,j} \Lambda^e v_{n+1,i}} \Theta(F_n^{ij}(a), a) \right) \otimes z.
\]
This completes the proof. \(\square\)
Corollary 7.5. Fix integers $c_n, X_{n,j} \in \mathbb{N}$ for $n \in \mathbb{N}$ and $1 \leq j \leq c_n$. Suppose that for each $n$, $\psi_n : \bigoplus_{j=1}^{c_n} M_{X_{n,j}}(C(T)) \to \bigoplus_{i=1}^{n+1} M_{X_{n+1,i}}(C(T))$ is a unital inclusion in which all nonzero partial inclusions $\psi_{n,j} : M_{X_{n,j}}(C(T)) \hookrightarrow M_{X_{n+1,i}}(C(T))$ are standard permutation mappings. Then there is a rank-2 Bratteli diagram $\Lambda$ in which all red cycles have length 1 such that $PC^*(\Lambda) P \cong \lim\langle \bigoplus_{j=1}^{c_n} M_{X_{n,j}}(C(T)), \psi_n \rangle$.

Proof. We may assume without loss of generality that for each $n \in \mathbb{N}$ and each $1 \leq j \leq c_n$ there exists $1 \leq i \leq c_{n+1}$ so that $\psi_{n,j} \neq 0$. For each $n \in \mathbb{N}$ and $1 \leq i \leq c_{n+1}$ there exists $1 \leq j \leq c_n$ such that $\psi_{n,j} \neq 0$ because each $\psi_n$ is unital.

For each $n, i, j$ such that $\psi_{n,j} \neq 0$, let $\sigma_{n,j}^i$ be the permutation such that $\psi_{n,j} = \psi_{n,j}^i$. When $\psi_{n,j} \neq 0$, we define $A_n(i, j)$ to be the size of the set of letters acted upon by $\sigma_{n,j}^i$ and regard $\sigma_{n,j}^i$ as a permutation of $\{1, 2, \ldots, A_n(i, j)\}$. If $\psi_{n,j} = 0$, we define $A_n(i, j) = 0$.

The previous paragraph shows that the matrices $A_n$ obtained in this way are all proper.

We construct $\Lambda$ as follows. Each $V_n$ contains $c_n$ vertices $\{v_{n,1}, \ldots, v_{n,c_n}\}$. Each vertex $v_{n,j}$ hosts a single red loop $\lambda_{n,j}$. Insert blue edges $\{e(l) : 1 \leq l \leq A_n(i, j)\}$ from $v_{n+1,i}$ to $v_{n,j}$ for each $n, i, j$. Specify the commuting squares by $\lambda_{n,j} a(\sigma_{n,j}^i(l)) = a(l) \lambda_{n+1,i}$. This data specifies a unique rank-2 Bratteli diagram $\Lambda$ by [23] page 101]. Proposition [23] implies that $PC^*(\Lambda) P \cong \lim\langle \bigoplus_{j=1}^{c_n} M_{X_{n,j}}(C(T)), \psi_n \rangle$. □

8. Real-rank and the trace simplex

The results of this section are inspired by Goodearl’s paper [14]. In this section we continue to use the notation established in Section 7. Let $\sigma$ be the cyclic permutation $\psi_m = \psi_\sigma$ satisfies

$$
\psi_m(f)(z) \sim_u \begin{pmatrix}
    f(z) & 0 & \cdots & 0 \\
    0 & f(\omega z) & \cdots & 0 \\
    \vdots & \vdots & \ddots & \vdots \\
    0 & 0 & \cdots & f(\omega^{m-1} z)
  \end{pmatrix}, \quad f \in C(T), \ z \in T,
$$

where $\omega = \exp(2\pi i/m)$. A general permutation $\sigma$ on $m$ letters is the product of disjoint cycles $\sigma_1 \sigma_2 \cdots \sigma_r$ (where we include all 1-cycles). Let $\ell_j$ denote the order of $\sigma_j$ (or, equivalently, the length of the cycle $\sigma_j$). Then $\psi_\sigma$ is unitarily equivalent (by a permutation unitary) to the direct sum $\bigoplus_{j=1}^r \psi_{\ell_j}$. Moreover $\psi_\sigma$ is unitarily equivalent (again with a permutation unitary) to the direct sum $\bigoplus_{\ell} 1_{c_\ell}(\sigma) \otimes \psi_\ell$, where $1_\ell \otimes \psi$ denotes the $c$-fold direct sum of copies of $\psi$. Notice that $m = \sum_{\ell} c_\ell(\sigma)$ for all $\sigma \in S_m$.

There is a norm on the linear span of $\mathcal{M}(T)$ which on differences of elements from $\mathcal{M}(T)$ is the total variation: $\|\mu - \nu\| = |\mu - \nu| (T)$, and is equal to the operator norm of $\mu - \nu$ when viewed as a functional on $C(T)$.

Recall the definitions of $\hat{R}_k$ and $\hat{p}_k$ from page 29.

Lemma 8.1.

$$
\bigcap_{n=1}^{\infty} \mathrm{conv}\{\hat{R}_k(\mu) : k \geq n, \mu \in \mathcal{M}(T)\} = \{m\},
$$

where the closure is with respect to the norm-topology, and where $m$ denotes the Lebesgue measure (or the normalized Haar measure) on $T$. 

Proof. The Lebesgue measure $m$ is the unique rotation invariant measure in $\mathcal{M}(\mathbb{T})$, i.e., the only measure that satisfies $\hat{\rho}_\theta(m) = m$ for all $\theta \in \mathbb{R}$. In particular, $\hat{R}_k(m) = m$ for all $k$, so $m$ belongs to the left-hand side of (8.2). Suppose, conversely, that $\nu$ is any element belonging to the left-hand side of (8.2). We show that $\hat{\rho}_\theta(\nu) = \nu$ for all $\theta \in \mathbb{R}$. This will entail that $\nu = m$ and will complete the proof.

Let $f \in C(\mathbb{T})$ and let $\varepsilon > 0$ be given. Find $\delta > 0$ such that $\|\rho_\theta(f) - f\|_\infty \leq \varepsilon$ whenever $|\theta| \leq \delta$. Note that $\rho_\theta R_k = \rho_\theta R_k$ whenever $k \in \mathbb{N}$ and $\theta, \theta' \in \mathbb{R}$ satisfy $\theta - \theta' \in 2\pi k^{-1}\mathbb{Z}$. For any $k \geq \pi \delta^{-1}$ and for any $\theta \in \mathbb{R}$ we can choose $\theta' \in \mathbb{R}$ such that $|\theta'| \leq \delta$ and $\theta - \theta' \in 2\pi k^{-1}\mathbb{Z}$. Then, for any $\mu \in \mathcal{M}(\mathbb{T})$,

$$\| (\hat{\rho}_\theta \hat{R}_k \mu)(f) - (\hat{\rho}_\theta \mu)(f) \| = |\mu(\rho_\theta R_k(f) - R_k(f))| = |\mu(\rho_\theta R_k(f) - R_k(f))| = |\mu(R_k(\rho_\theta(f) - f))| \leq \| \rho_\theta(f) - f \| \leq \varepsilon.$$ 

Thus $|(\hat{\rho}_\theta \mu')(f) - \mu'(f)| \leq \varepsilon$ for all $\mu' \in \text{conv}\{\hat{R}_k(\mu) : k \geq \pi \delta^{-1}, \mu \in \mathcal{M}(\mathbb{T})\}$.

In particular, $|(\hat{\rho}_\theta \nu)(f) - \nu(f)| \leq \varepsilon$. As $f \in C(\mathbb{T})$ and $\varepsilon > 0$ were arbitrary it follows that $\hat{\rho}_\theta(\nu) = \nu$ for all $\theta \in \mathbb{R}$, as desired. \qed

Let $\text{tr}_n$ denote the normalized trace on $M_n$, and for $\mu \in \mathcal{M}(\mathbb{T})$ and $n \in \mathbb{N}$, let $\text{tr}_{n, \mu}$ denote the normalized trace on $M_n(C(\mathbb{T}))$ given by

\begin{equation}
\text{tr}_{n, \mu}(f) = \int_{\mathbb{T}} \text{tr}_n(f(z)) \, d\mu(z), \quad f \in M_n(C(\mathbb{T})).
\end{equation}

Every tracial state on $M_n(C(\mathbb{T}))$ is of the form $\text{tr}_{n, \mu}$ for some $\mu \in \mathcal{M}(\mathbb{T})$.

Consider again the unital $^*$-homomorphism $\psi_\sigma : M_n(C(\mathbb{T})) \to M_{mn}(C(\mathbb{T}))$ associated to a permutation $\sigma \in S_m$. The induced mapping $T(\psi_\sigma) : T(M_{mn}(C(\mathbb{T}))) \to T(M_n(C(\mathbb{T})))$ is by (7.1) and (8.1) given as follows:

\begin{equation}
\forall \mu_1, \mu_2 \in \mathcal{M}(\mathbb{T}) : \text{tr}_{nm, \mu_2} \circ \psi_\sigma = \text{tr}_{n, \mu_1} \iff \mu_1 = \sum_{\ell} \frac{\ell c_{\ell}(\sigma)}{m} \hat{R}_\ell(\mu_2).
\end{equation}

We shall often use the next identity, that holds for any $n \in \mathbb{N}$ and any $\mu, \nu \in \mathcal{M}(\mathbb{T})$:

\begin{equation}
\| \text{tr}_{n, \mu} - \text{tr}_{n, \nu} \| = \| \mu - \nu \|.
\end{equation}

Finally recall that if $\{s_j\}_{j=1}^{\infty}$ is a sequence in $(0, 1]$, then

\begin{equation}
\prod_{j=1}^{\infty} s_j > 0 \iff \sum_{j=1}^{\infty} (1 - s_j) < \infty.
\end{equation}

We remind the reader again that for a permutation $\sigma$, the quantities $\kappa(\sigma), c_{\ell}(\sigma)$ and $\beta_N(\sigma)$ are defined in Definition 7.1 and that the Markov operators $R_k$ and $\hat{R}_k$ and the standard permutation mapping $\psi_\sigma$ are defined on pp. 29–30.

**Theorem 8.2.** Consider a direct limit of $C^*$-algebras

\begin{equation}
\bigoplus_{i=1}^{r_1} M_{n_1,i}(C(\mathbb{T})) \xrightarrow{\varphi_1} \bigoplus_{i=1}^{r_2} M_{n_2,i}(C(\mathbb{T})) \xrightarrow{\varphi_2} \bigoplus_{i=1}^{r_3} M_{n_3,i}(C(\mathbb{T})) \to \cdots \to A,
\end{equation}

with unital connecting maps $\varphi_j$. Let $A_j$ denote the $j^{th}$ algebra in the sequence, so that $A_j = \bigoplus_{i=1}^{r_j} A_{j,i}$, where $A_{j,i} = M_{n_{j,i}}(C(\mathbb{T}))$. Suppose that each of the partial mappings
\( \varphi_{j}^{s,t} : A_{j,s} \to A_{j+1,t} \) induced by \( \varphi_{j} \) either is zero or is a standard permutation mapping, say of the form \( \psi_{\sigma_{j}^{s,t}} \), where \( \sigma_{j}^{s,t} \) is a permutation on \( m_{j}^{s,t} \) letters. Set

\[
X_{j} = \{(s,t) : 1 \leq t \leq r_{j}, 1 \leq s \leq r_{j+1}, \varphi_{j}^{s,t} \neq 0 \} \quad \text{and} \quad X_{j}(t) = \{s : (s,t) \in X_{j}\}.
\]

Let \( B \) be the AF-algebra associated with the inductive limit in \([S, \tau]\), defined as follows. Let \( B_{j} \subseteq A_{j} \) be the sub-C*-algebra consisting of all constant functions (so that \( B_{j} = \bigoplus_{i=1}^{r_{j}} M_{n_{j,i}} \)), and observe that \( \varphi_{j}(B_{j}) \subseteq B_{j+1} \). Set

\[
B = \bigcup_{j=1}^{\infty} \varphi_{\infty,j}(B_{j}) \subseteq A,
\]

where \( \varphi_{\infty,j} : A_{j} \to A \) is the inductive limit map; or equivalently, \( B \) is the inductive limit of the sequence \( B_{1} \to B_{2} \to B_{3} \to \cdots \).

Suppose that \( B \) is simple. Then:

(i) \( A \) is simple if and only if \( \sup \{ \kappa(\sigma_{j}^{s,t}) : j \in \mathbb{N}, (s,t) \in X_{j} \} = \infty \).

For each natural number \( N \), set

\[
\alpha_{N} = \sum_{j=1}^{\infty} (1 - \beta(N,j)), \quad \overline{\alpha}_{N} = \sum_{j=1}^{\infty} (1 - \overline{\beta}(N,j)).
\]

(ii) If \( \alpha_{N} = \infty \) for all natural numbers \( N \), then \( A \) is simple with real-rank zero, and the inclusion mapping \( B \to A \) induces an isomorphism \( T(A) \to T(B) \) at the level of traces.

(iii) If \( \overline{\alpha}_{N} < \infty \) for some \( N \), then \( A \) has real-rank one, and there is an injective mapping

\[
\left( T(B) \times \{ \mu \in \mathcal{M}(\mathbb{T}) : \widehat{R}(\mu) = \mu \} \right) \to T(A), \quad (\tau, \mu) \mapsto \overline{\tau}_{\mu},
\]

such that each \( \overline{\tau}_{\mu} \) extends \( \tau \).

(iv) Suppose that each \( r_{j} = 1 \) so each \( A_{j} \) has just a single direct summand. Then \( B \) is a UHF algebra and the quantities \( \overline{\alpha}_{N} \) and \( \overline{\alpha}_{N} \) coincide for all \( N \). If \( \overline{\alpha}_{1} < \infty \) then the injection of part (iii) is continuous and affine. If \( \underline{\alpha}_{1} < \infty \), then the injection of part (iii) is a homeomorphism of \( \mathcal{M}(\mathbb{T}) \) onto \( T(A) \).

**Proof.** We can and will assume that the restriction of each \( \varphi_{j} \) to each summand \( A_{j,s} \) is non-zero. This will ensure that the connecting maps \( \varphi_{j} \) are injective.

The connecting mapping \( A_{j} \to A_{i} \), for \( j < i \), is denoted by \( \varphi_{i,j} \), and the corresponding partial mapping \( A_{j,t} \to A_{i,s} \) is denoted by \( \varphi_{i,j}^{s,t} \). As already mentioned, we let \( \varphi_{\infty,j} \) denote the inductive limit mapping \( A_{j} \to A \). We identify each \( A_{j,s} \) with a sub-C*-algebra of \( A_{j} \), let \( \pi_{j,s} : A_{j} \to A_{j,s} \) be the natural conditional expectation, and denote the unit of \( A_{j,s} \) by \( e_{j,s} \).

Note that \( f e_{j,s} = \pi_{j,s}(f) \) for \( f \in A_{j} \). Note also that the projections \( \{ \varphi_{\infty,j}(e_{j,s}) \} \) separate traces on \( B \).

(i). It suffices to show that \( \varphi_{\infty,j}(f) \) is full in \( A \) for \( j \in \mathbb{N} \) and \( f \in A_{j} \setminus \{0\} \). Given a non-zero \( f \) in \( A_{j} \), then \( \pi_{j,t_{0}}(f) \neq 0 \) for some \( t_{0} = 1, \ldots, r_{j} \). Take any non-zero element \( b_{0} \) in \( B_{j} \cap A_{j,t_{0}} \). Because \( B \) is simple and the connecting maps are unital and injective there is \( j' > j \) such that \( \varphi_{j',j}(b_{0}) \) is full in \( B_{j'} \) (and hence in \( A_{j'} \)).

For each \( i \geq j \) and for each \( s = 1, \ldots, r_{i} \) put

\[
U_{i,s} = \{ z \in \mathbb{T} : (\pi_{i,s} \circ \varphi_{i,j})(f)(z) \neq 0 \} \subseteq \mathbb{T}.
\]
Suppose that $\varphi_i^{s,t} \neq 0$. Use (8.8) and the fact that $\varphi_i^{s,t} = \psi_i^{s,t}$ is unitarily equivalent to $\bigoplus_k 1_{c_k(\sigma_i^{s,t})} \otimes \psi_k$, to conclude that $U_{i,t} \subseteq U_{i+1,s}$, and that $U_{i+1,s} = \mathbb{T}$ if $U_{i,t}$ contains a closed connected arc of length at least $2\pi \kappa(\sigma_i^{s,t})^{-1}$.

The set $U := U_{j,t_0}$ is non-empty because $\pi_{j,t_0} (f) \neq 0$. The partial mapping $\varphi_{j,t_0}$ which takes $A_{j,t_0}$ to $A_{i,s}$ is non-zero for all $i \geq j'$ and for all $j = 1, \ldots, n$, because $\varphi_{i,j}(b_0)$ is full in $A_i$ whenever $i \geq j'$. The argument above therefore shows that $U \subseteq U_{i,s}$ for all $i \geq j'$ and for all $s$. The assumption that $\{\kappa(\sigma_i^{s,t})\}$ is unbounded implies that there is $i \geq j'$ and $(s,t) \in X_j$ such that $U$ contains a closed connected arc of length at least $2\pi \kappa(\sigma_i^{s,t})^{-1}$. Thus $U_{i+1,s} = \mathbb{T}$, or, in other words, $(\pi_{i+1,s} \circ \varphi_{i+1,j})(f)$ is full in $A_{i+1,s}$. This shows that the ideal in $A$ generated by $\varphi_\infty (f)$ contains $\varphi_\infty, i+1(A_{i+1,s})$, and hence has non-zero intersection with $B$, so $A$ is non-empty.

Suppose now that $(\kappa(\sigma_i^{s,t}))$ is bounded. Then there is a natural number $N$ such that $\ell \mid N$ for all $\ell$ for which $c_\ell (\sigma_j^{s,t}) \neq 0$ for some $j$ and some $(s,t) \in X_j$. Let $g_{N,j} \in A_j = C(\mathbb{T}, B_j)$ be given by $g_{N,j}(z) = z^N 1_{B_j}$. It follows from (7.5) that $\varphi_j (g_{N,j}) = g_{N,j+1}$ for all $j$. As $g_{N,j}$ is central in $A_j$ for all $j$, $\varphi_\infty (g_{N,1})$ belongs to the centre of $A$. Hence $A$ has non-trivial centre, so $A$ is non-simple.

(ii) and (iii). Each tracial state $\tau_j$ on $A_j$ is of the form

$$
\tau_j(f) = \sum_{t=1}^{r_j} a_{j,t} tr_{n_j,t,\mu_{j,t}}(\pi_j, t(f)),
$$

for some $\mu_{j,1}, \ldots, \mu_{j,r_j} \in M(\mathbb{T})$ where each $a_{j,t} \geq 0$ is the value $\tau_j(e_{j,t})$ of $\tau$ at the unit $e_{j,t}$ for $A_{j,t}$. We show first that if $\tau_j$ and $\tau_{j+1}$ are traces on $A_j$ and $A_{j+1}$, respectively, given as in (8.8), if $\tau_{j+1} \circ \varphi_j = \tau_j$, and if $a_{j,t} \neq 0$, then

$$
\mu_{j,t} = \sum_{s \in X_j(t)} a_{j+1,s} m_j^{s,t} n_{j,t} \sum \ell \frac{\ell c_\ell (\sigma_j^{s,t})}{m_j^{s,t}} \hat{R}_\ell (\mu_{j+1,s}),
$$

and

$$
1 = \sum_{s \in X_j(t)} a_{j+1,s} m_j^{s,t} n_{j,t} \sum \ell \frac{\ell c_\ell (\sigma_j^{s,t})}{m_j^{s,t}}.
$$

The second identity in (8.10) follows by the definition of the coefficients $c_\ell$. The first identity in (8.10) follows from the calculation:

$$
a_{j,t} = \tau_j(e_{j,t}) = \tau_j(\varphi_j(e_{j,t}))
= \sum_{s \in X_j(t)} a_{j+1,s} tr_{n_{j+1,s},\mu_{j+1,s}}(\varphi_j^{s,t}(e_{j,t}))
= \sum_{s \in X_j(t)} a_{j+1,s} m_j^{s,t} n_{j,t} n_{j+1,s},
$$

where we have used that $\dim(e_{j,t}) = n_{j,t}$ and that the multiplicity of $\varphi_j^{s,t}$ is $m_j^{s,t}$. We proceed to prove (8.9). Two applications of (8.8) yield

$$
a_{j,t} tr_{n_{j,t},\mu_{j,t}} = \tau_j \circ \pi_{j,t} = \tau_{j+1} \circ \varphi_j \circ \pi_{j,t} = \sum_{s \in X_j(t)} a_{j+1,s} tr_{n_{j+1,s},\mu_{j+1,s}}(\psi_{j,s,t}).
$$
We wish to apply (8.4) to right-hand side of (8.11), but we must take into account that the *-homomorphism \( \varphi_{j,t}^{s,t} : A_j, t \to A_{j+1, s} \) is not unital. This is done by adjusting the right-hand side of (8.11) by the factor \( \dim(\varphi_{j,t}^{s,t}(e_{j,t})) / n_{j+1,s} = n_{j,t} m_{s,t}^{j,t} / n_{j+1,s}. \) Now, (8.9) follows from (8.11) and from the modified (8.4).

For any natural number \( N \) we rewrite (8.9) as

\[
\mu_{j,t} = \sum_{s \in X_j(t)} a_{j,t} m_{s,t} \left( \sum_{\ell \in N} \frac{\ell c_{\ell}(\sigma_{j,t}^{s,t})}{m_{s,t}^{j,t}} \tilde{R}_\ell(\mu_{j+1,s}) + \sum_{\ell \not\in N} \frac{\ell c_{\ell}(\sigma_{j,t}^{s,t})}{m_{s,t}^{j,t}} \tilde{R}_\ell(\mu_{j+1,s}) \right)
\]

\[
= \sum_{s \in X_j(t)} \sum_{\gamma_{N,j}^{s,t}} E_{N,j}^{s,t}(\mu_{j+1,s}) + \sum_{s \in X_j(t)} \eta_{N,j}^{s,t} F_{N,j}^{s,t}(\mu_{j+1,s}),
\]

where \( E_{N,j}^{s,t} \subseteq \text{conv}\{R_k : k \mid N\} \), \( F_{N,j}^{s,t} \subseteq \text{conv}\{R_k : k \not\mid N\} \), and for \( s, t \in X_j \),

\[
\gamma_{N,j}^{s,t} = \frac{a_{j,t} m_{s,t} n_{j,t}}{n_{j+1,s}} \beta_{N}(\sigma_{j,t}^{s,t}), \quad \eta_{N,j}^{s,t} = \frac{a_{j,t} m_{s,t} n_{j,t}}{n_{j+1,s}}(1 - \beta_{N}(\sigma_{j,t}^{s,t})).
\]

Put \( \gamma_{N,j}^{s,t} = \eta_{N,j}^{s,t} = 0 \) if \( (s, t) \notin X_j \). Note that \( \sum_{s=1}^{r_{j+1}} (\gamma_{N,j}^{s,t} + \eta_{N,j}^{s,t}) = 1 \), and that

\[
\beta(N, j) \leq \sum_{s=1}^{r_{j+1}} \gamma_{N,j}^{s,t} = \sum_{s=1}^{r_{j+1}} \eta_{N,j}^{s,t} \leq \beta(N, j).
\]

Suppose now that we have a tracial state \( \tau_j \) on \( A_j \) for all \( j \) (given as in (8.8) above) such that \( \tau_{j+1} \circ \varphi_{j} = \tau_{j} \) holds for all \( j \). It then follows from iterated use of the identities established above, together with (8.13), that for \( i > j, t = 1, \ldots, r_{j+1}, \) and \( s = 1, \ldots, r_i \),

\[
\mu_{j,t} = \sum_{s=1}^{r_i} \gamma_{N,i,j}^{s,t} E_{N,i,j}^{s,t}(\mu_{i,s}) + \sum_{s=1}^{r_i} \eta_{N,i,j}^{s,t} F_{N,i,j}^{s,t}(\mu_{i,s}),
\]

where \( E_{N,i,j}^{s,t} \subseteq \text{conv}\{R_k : k \mid N\} \), \( F_{N,i,j}^{s,t} \subseteq \text{conv}\{R_k : k \not\mid N\} \), and where \( \gamma_{N,i,j}^{s,t} \) and \( \eta_{N,i,j}^{s,t} \) are non-negative real numbers satisfying

\[
\sum_{s=1}^{r_i} (\gamma_{N,i,j}^{s,t} + \eta_{N,i,j}^{s,t}) = 1, \quad \sum_{s=1}^{r_i} \gamma_{N,i,j}^{s,t} \leq \prod_{k=j}^{i-1} \beta(N, k).
\]

(ii) We first show that each tracial state \( \tau \) on \( B \) lifts to a tracial state \( \overline{\tau} \) on \( A \). Indeed, for each \( j \in \mathbb{N} \), let \( \overline{\tau}_j \) be the trace on \( A_j \) given as in (8.8) with

\[
a_{j,t} = \tau(\varphi_{\infty,j}(e_{j,t})), \quad \mu_{j,t} = m, \quad t = 1, \ldots, r_j,
\]

(whence is the Lebesgue measure). Since \( \tilde{R}_\ell(m) = m \) for all \( \ell \) it follows from (8.9) that \( \overline{\tau}_{j+1} \circ \varphi_{j} = \overline{\tau}_{j} \) for all \( j \), and so there is a trace \( \overline{\tau} \) on \( A \), which satisfies \( \overline{\tau} \circ \varphi_{\infty,j} = \overline{\tau}_{j} \) for all \( j \). (The first equation in (8.10) holds because \( \tau \) is a trace on \( B \).) In particular,

\[
\tau(\varphi_{\infty,j}(e_{j,t})) = a_{j,t} = \overline{\tau}_j(e_{j,t}) = \overline{\tau}(\varphi_{\infty,j}(e_{j,t})).
\]

Since \( \{\varphi_{\infty,j}(e_{j,t})\} \) separate traces on \( B \) we conclude that \( \overline{\tau}|_B = \tau \).

We now show that the lift constructed above is unique. Here we need our assumption that \( \alpha_N = \infty \) for all \( N \). Let again \( \tau \) be a tracial state on \( B \) and suppose that \( \overline{\tau} \) is (another) tracial state on \( A \) that extends \( \tau \). Then

\[
a_{j,t} := \overline{\tau}(\varphi_{\infty,j}(e_{j,t})) = \tau(\varphi_{\infty,j}(e_{j,t})).
\]
Now, \( \tilde{\tau}_j := \tilde{\tau} \circ \varphi_{\infty,j} \) is a trace on \( A_j \) which therefore is given as in (8.8) with \( a_{j,t} \) as above and with respect to some measures \( \mu_{j,1}, \ldots, \mu_{j,r_j} \in \mathcal{M}(\mathbb{T}) \). We must show that \( \mu_{j,t} = m \) for all \( j \) and \( t \). (This will show that \( \tilde{\tau} = \tau \), cf. the construction of \( \tau \) above.)

The assumption that \( \alpha_N = \infty \) implies that

\[
\lim_{i \to \infty} \prod_{k=j}^{i-1} \| \tilde{\tau}(N, j) \| = 0
\]

for all \( j, N \in \mathbb{N} \), cf. (8.6). It follows from equations (8.12) and (8.13) that \( \mu_{j,t} \) belongs to the norm closure of \( \text{conv}\{R_k : k \geq n\} \) for all \( N \), and hence, upon choosing \( N = (n-1)! \), that \( \mu_{j,t} \) belongs to the norm closure of \( \text{conv}\{R_k : k \geq n\} \) for all \( n \). By Lemma 8.1 this implies that \( \mu_{j,t} = m \), as desired.

We use (i) to show that \( A \) is simple. Let \( n \) be a natural number and put \( N = (n-1)! \). Since \( \alpha_N = \infty \), there exist \( j, s, t \) such that \( \beta_N(\sigma^s,t) < 1 \). This implies that \( \kappa(\sigma^s,t) \geq n \). Hence \( \{\kappa(\sigma^s,t)\} \) is unbounded.

Projections in \( B \) separate traces on \( B \) because \( B \) is of real rank zero, being an AF-algebra. We have shown that each trace in \( B \) has a unique lift to a trace on \( A \). It follows that projections in \( B \) (and hence also projections in \( A \)) separate traces on \( A \). We can therefore use [2] Theorem 1.3] to conclude that \( A \) has real-rank zero.

(iii). Assume that \( \tau_N < \infty \) for some \( N \). We construct an injective mapping

\[
T(B) \times \{ \mu \in \mathcal{M}(\mathbb{T}) : \hat{R}_N(\mu) = \mu \} \to T(A), \quad (\tau, \mu) \mapsto \tilde{\tau}_\mu,
\]

such that each \( \tilde{\tau}_\mu \) extends \( \tau \).

Let \( \tau \in T(B) \) and let \( \mu \in \mathcal{M}(\mathbb{T}) \) with \( \hat{R}_N(\mu) = \mu \) be given. We proceed to construct the tracial state \( \tilde{\tau}_\mu \) on \( A \) that extends \( \tau \). Let \( \tilde{\tau}_{\mu,j} \) be the trace on \( A_j \) given as in (8.8) with

\[
a_{j,t} = \tau(\varphi_{\infty,j}(e_{j,t})), \quad \mu_{j,t} = \mu, \quad t = 1, \ldots, r_j.
\]

Use (8.9), (8.10) and (8.5) to see that

\[
\| \tilde{\tau}_{\mu,i+1} \circ \varphi_i - \tilde{\tau}_{\mu,i} \| \leq \sum_{t=1}^{r_j} a_{i,t} \left( \sum_{s \in X_i(t)} \frac{a_{i+1,s} m^s_{i,n_{i,t}} \ell \left( \sigma^s,t \right)}{m^s_{i,t}} \left( \hat{R}_{\mu} - \mu \right) \right)
\]

\[
= \sum_{t=1}^{r_j} a_{i,t} \left( \sum_{s \in X_i(t)} \frac{a_{i+1,s} m^s_{i,n_{i,t}} \ell \left( \sigma^s,t \right)}{m^s_{i,t}} \left( \hat{R}_{\mu} - \mu \right) \right)
\]

\[
\leq \sum_{t=1}^{r_j} a_{i,t} \left( \sum_{s \in X_i(t)} \frac{a_{i+1,s} m^s_{i,n_{i,t}} \ell \left( \sigma^s,t \right)}{m^s_{i,t}} \left( \hat{R}_{\mu} - \mu \right) \right)
\]

\[
\leq \sum_{t=1}^{r_j} a_{i,t} \left( \sum_{s \in X_i(t)} \frac{a_{i+1,s} m^s_{i,n_{i,t}} \ell \left( \sigma^s,t \right)}{m^s_{i,t}} \left( 1 - \beta(\delta(i)) \right) \right)
\]

\[
= 1 - \beta(\delta(i)).
\]

The hypothesis \( \tau_N = \sum_{k=1}^{\infty} (1 - \beta(\delta(\delta(k))) < \infty \) implies that \( \delta_i := \sum_{k=1}^{\infty} (1 - \beta(\delta(\delta(k))) \to 0 \) as \( i \to \infty \). We deduce that \( \{ \tilde{\tau}_{\mu,i} \circ \varphi_{i,j} \}_{i,j} \) is a Cauchy sequence in norm, and thus converges to a trace \( \tilde{\tau}_{\mu,j} \) on \( A_j \) which satisfies \( \| \tilde{\tau}_{\mu,j} - \tilde{\tau}_{\mu,j} \| \leq \delta_j \). As \( \tilde{\tau}_{\mu,j+1} \circ \varphi_j = \tilde{\tau}_{\mu,j} \)

for all \( j \), there is a tracial state \( \tilde{\tau}_\mu \) on \( A \) such that \( \tilde{\tau}_\mu \circ \varphi_{\infty,j} = \tilde{\tau}_{\mu,j} \) for all \( j \).
To show that $\tau$ extends $\tau$ observe first that $\varphi^j(\mu, t) = a_{j,t} = (\tau \circ \varphi_j)(\mu, t)$ for all $j$ and $t$, and hence that the restriction of $\varphi^j$ to $B_j$ is equal to $\tau \circ \varphi_j$. As $\varphi^{ij} \circ \varphi^i_j \to \varphi_j$, the restriction of $\varphi \circ \varphi_j$ to $B_j$ is equal to $\tau \circ \varphi_j$ for all $j$. Hence $\tau$ extends $\tau$.

Assume that $\mu, \nu \in M(T)$ are such that $\hat{R}_N(\mu) = \mu$, $\hat{R}_N(\nu) = \nu$, and $\tau = \tau$. Then, using (a slightly modified version of) (8.5),

$$\|\mu - \nu\| \leq \|\varphi^j(\mu) - \varphi^j(\nu)\| + \|\varphi^j \circ \varphi_j(\mu) - \varphi^j \circ \varphi_j(\nu)\| + \|\varphi^j \circ \varphi_j(\mu) - \varphi^j \circ \varphi_j(\nu)\| \\ \leq \|\varphi^j(\mu) - \varphi^j(\nu)\| + \|\varphi^j \circ \varphi_j(\mu) - \varphi^j \circ \varphi_j(\nu)\| + \|\varphi^j \circ \varphi_j(\mu) - \varphi^j \circ \varphi_j(\nu)\| \\ \leq 2\delta_j,$$

for all $j$, which entails that $\mu = \nu$.

We claim that $\tau(\mu) = \tau(\nu)$ for every projection $p \in A$. To see this, note that each projection $p \in A$ is equivalent to $\varphi_j(q)$ for some projection $q$ in some $A_j$. Now, each projection $q$ in $A_j$ is equivalent to a projection $q'$ in $B_j$, so $p$ is equivalent to the projection $p' = \varphi_j(q)$. This proves that $\tau(\mu(p)) = \tau(\nu(p)) = \tau(p) = \tau(p') = \tau(p)$, establishing the claim.

The stable rank of any AT-algebra is one, and hence its real rank must be either zero or one. The claim above and that $\tau = \tau$ whenever $\mu$ and $\nu$ are distinct measures fixed under $\hat{R}_N$ show that projections in $A$ do not separate traces on $A$. Hence $\tau$ cannot be of real rank zero, and must therefore be of real rank one.

(iv). Suppose now that $r_n = 1$ for all $n$. Then $B$ is a direct limit of unital inclusions of simple finite-dimensional $C^*$-algebras, and hence is UHF, and in particular is simple and has unique trace $\tau^B$. It is immediate from the definitions of $\hat{R}_N$ and $\tau_N$ that these quantities coincide for all $N$. If $\hat{R}_N = \tau_N < \infty$, then injection of statement (iii) depends on only one variable as $T(B) = \{\tau^B\}$. Hence we write $\tau^B$ rather than $\tau_B^B$ for the trace on $A$ corresponding to a given $\mu \in M(T)$. Since each $B_j$ has just one summand $B_{j,1}$ we will drop the second subscript henceforth, and write $B_j$ for $B_{j,1}$, $n_j$ for $n_{j,1}$, etc. The $j$th approximating algebra $B_j$ has unique trace $\tau_{n_j}$, so we can use (8.12) and the subsequent paragraph to deduce that

$$\|\tau^B \circ \varphi_j - \tau_{n_j} \circ \varphi_j\| \leq \delta_j \to 0.$$  

Since $\mu \mapsto \tau_{n_j}$ is affine, we conclude that $\mu \mapsto \tau^B$ is affine.

To see that the map $\mu \mapsto \tau^B$ is continuous, take a net $\{\mu_\alpha\}$ in $M(T)$ which converges in the weak-* topology to $\mu \in M(T)$. To show that $\tau_{\mu_\alpha} \to \tau^B_{\mu}$ it suffices to show that $\tau_{\mu_\alpha} \to \tau^B_{\mu}$ for all $a$ in the dense subset $\bigcup_{j=1}^\infty \varphi_{j}(A_j)$ of $A$. In other words, it suffices to show that $\tau_{\mu_\alpha} \circ \varphi_{j}(f) \to \tau^B_{\mu} \circ \varphi_{j}(f)$ for all $f \in A_j$. But if $g : A_j \to \mathbb{C}$ is the function $g(z) = \tau_{n_j}(f(z))$, then

$$\tau_{\mu_\alpha} \circ \varphi_{j}(f) = \mu_\alpha(g) \to \mu(g) = \tau^B_{\mu} \circ \varphi_{j}(f).$$

Finally, suppose that $\alpha_1 < \infty$. We show that $\mu \mapsto \tau^B_{\mu}$ is surjective, and being a continuous bijection between compact sets, it must then be a homeomorphism.
Fix $\tau \in T(A)$. Then $\tau \circ \varphi_{i,j}$ is a trace on $A_j$, and is hence equal to $\text{tr}_{n_j,j}$. Since $\text{tr}_{n_j+1,j} \circ \varphi = \text{tr}_{n_j,j}$ we can use (8.4) to estimate
\[
\|\mu_j - \mu_{j+1}\| = \left\| \sum_{\ell} \frac{\ell c_\ell(\sigma_j)}{m_j} \hat{R}_\ell(\mu_{j+1}) - \mu_{j+1} \right\|
\]
\[
= \left\| \sum_{\ell>1} \frac{\ell c_\ell(\sigma_j)}{m_j} (\hat{R}_\ell(\mu_{j+1}) - \mu_{j+1}) \right\|
\]
\[
\leq \sum_{\ell>1} \frac{\ell c_\ell(\sigma_j)}{m_j}
\]
\[
= 1 - \beta(1,j).
\]

We have assumed that $\alpha_1 = \sum_{j=1}^{\infty} (1 - \beta(1,j)) < \infty$. Hence $\{\mu_j\}$ is norm convergent to a measure $\mu \in \mathcal{M}(\mathbb{T})$. Moreover,
\[
\|\tau^B_{\mu} \circ \varphi_{i,j} - \tau \circ \varphi_{i,j}\| = \|\tau^B_{\mu} \circ \varphi_{i,j} - \text{tr}_{n_j,j}\|
\]
\[
\leq \|\tau^B_{\mu} \circ \varphi_{i,j} - \text{tr}_{n_j,j}\| + \|\text{tr}_{n_j,j} - \text{tr}_{n_j,j}\|
\]
\[
= \delta_j + \|\mu - \mu_j\| \rightarrow 0, \quad \text{by (8.15)}
\]
which proves that $\tau = \tau^B_{\mu}$. \hfill \Box

**Proof of Theorem 7.2.** The 1-graph of Proposition 4.9 is $f^*_i \Lambda$ and $Q$ is equal to $P$. Hence $C^*(f^*_i \Lambda)$ is AF, and is simple if and only if $f^*_i \Lambda$ (equivalently $\Lambda$) is cofinal \[19\]. The simplicity statement for $C^*(\Lambda)$ follows from Theorem 5.1(1). Proposition 7.3 shows that the partial inclusions in the direct limit decomposition of $C^*(\Lambda)$ are standard inclusions with permutations $(\mathcal{F}^{i,j}_n)^{-1}$. Moreover, the approximating subalgebras $F_n$ in $C^*(f^*_i \Lambda)$ from Proposition 4.9 are the subalgebras of constant functions in the approximating subalgebras of $C^*(\Lambda)$, so $C^*(f^*_i \Lambda)$ is the AF algebra $B$ associated to $C^*(\Lambda)$ in Theorem 8.2. Since each $\kappa((\mathcal{F}^{i,j}_n)^{-1}) = \kappa(\mathcal{F}^{i,j}_n)$ and each $\ell((\mathcal{F}^{i,j}_n)^{-1}) = \ell(\mathcal{F}^{i,j}_n)$, the remaining statements of the theorem now follow from Theorem 8.2. \hfill \Box
